Hortonworks Data Platform: Apache Ambari Views

Copyright © 2012-2016 Hortonworks, Inc. All rights reserved.

The Hortonworks Data Platform, powered by Apache Hadoop, is a massively scalable and 100% open source platform for storing, processing and analyzing large volumes of data. It is designed to deal with data from many sources and formats in a very quick, easy and cost-effective manner. The Hortonworks Data Platform consists of the essential set of Apache Hadoop projects including MapReduce, Hadoop Distributed File System (HDFS), HCatalog, Pig, Hive, HBase, ZooKeeper and Ambari. Hortonworks is the major contributor of code and patches to many of these projects. These projects have been integrated and tested as part of the Hortonworks Data Platform release process and installation and configuration tools have also been included.

Unlike other providers of platforms built using Apache Hadoop, Hortonworks contributes 100% of our code back to the Apache Software Foundation. The Hortonworks Data Platform is Apache-licensed and completely open source. We sell only expert technical support, training and partner-enablement services. All of our technology is, and will remain free and open source. Please visit the Hortonworks Data Platform page for more information on Hortonworks technology. For more information on Hortonworks services, please visit either the Support or Training page. Feel free to Contact Us directly to discuss your specific needs.

1. Using Ambari Views

Ambari includes the Ambari Views Framework, which allows for developers to create UI components that "plug into" the Ambari Web interface. Ambari includes a built-in set of Views that are pre-deployed for you to use with your cluster. This guide provides information on configuring the built-in set of Views, as well as information on how to configure Ambari Server for "standalone" operation.

Views can be deployed and managed in the "operational" Ambari Server that is operating your cluster. In addition, Views can be deployed and managed in one or more separate "standalone" Ambari Servers. Running "standalone" Ambari Server instances is useful when users who will access views will not have (and should not) have access to that Ambari Server that is operating the cluster. As well, you can run one or more separate Ambari Server instances "standalone" for a scale-out approach to handling a large number of users. See Running Ambari Standalone for more information.

Important

It is critical that you prepare your Ambari Server for hosting views. It is strongly recommended you increase the amount of memory available to your Ambari Server, and that you run additional "standalone" Ambari Servers to host the views. See Preparing Ambari Server for Views and Running Ambari Server Standalone for more information.

View Auto- Created*		Description	HDP Stacks	Required Services
Using the Yes Provides a visual way to configure YARN capacity YARN Queue scheduler queue capacity. Manager View [15]		HDP 2.3 or later	YARN	
Using the Files View [31]	Yes	Allows you to browse the HDFS file system.	HDP 2.2 or later	HDFS
Using the Hive View [42]	Yes	Exposes a way to find, author, execute and debug Hive queries.	HDP 2.3 or later	HDFS, YARN, Hive
		HDP 2.4 or later	Hue	
Using the Pig View [62]	No	Provides a way to author and execute Pig Scripts.	HDP 2.2 or later	HDFS, Hive, Pig
Using the Slider View [72] No A tool to help deploy and manage Slider-based applications. This view has been marked deprecated.		HDP 2.2 or later	HDFS, YARN	
		Allows you to capture bundles, set bundle capture schedule, and view and download captured bundles.	HDP 2.0 or later	SmartSense
Storm No Supports monitoring Storm cluster status and topologies.		HDP 2.5 or later	Storm	
Using the Tez Yes View information related to Tez jobs that are executing on the cluster.		HDP 2.2.4.2 or later	HDFS, YARN, Tez	
Workflow No This View is Tech Preview Designer		HDP 2.4 or later	Oozie	

View	Auto- Created*	Description	HDP Stacks	Required Services
Zeppelin	Yes	This View is Tech Preview	HDP 2.5 or later	Zeppelin

Ambari "Auto-creates" some views, if the service utilized by that view is added to the cluster. "Auto-create" means that Ambari creates and instance of the view and displays that instance to users via Ambari web, automatically. For other services, an Ambari Admin must create the view instance. For example, if YARN service is added to the cluster, the YARN Queue Manager View displays to Ambari Web users.

Learning More About Views

You can learn more about the Views Framework at the following resources:

Resource	URL	
Administering Views	ortonworks Data Platform Apache Ambari Administration - Managing Views	
Ambari Project Wiki	Project Wiki https://cwiki.apache.org/confluence/display/AMBARI/Views	
Example Views	ttps://github.com/apache/ambari/tree/trunk/ambari-views/examples	
View Contributions	https://github.com/apache/ambari/tree/trunk/contrib/views	

2. Preparing Ambari Server for Views

When hosting multiple views in Ambari, it is **strongly recommended** you increase the amount of memory available to the Ambari Server. Since each view requires it's own memory footprint, increasing the Ambari Server maximum available memory will help support multiple deployed views and concurrent use.

1. On the Ambari Server host, edit the ambari-env.sh file:

```
vi /var/lib/ambari-server/ambari-env.sh
```

2. For the AMBARI_JVM_ARGS variable, replace the default -Xmx2048m with the following:

-Xmx4096m -XX:PermSize=128m -XX:MaxPermSize=128m

3. Restart Ambari Server for this change to take effect.

ambari-server restart

If the Ambari Server instance is configured for HTTPS, a trust store must also be configured so that the deployed views are able to trust the certificate used by the Ambari Server during API communications. The process includes creating a trust store with the certificate that the Ambari Server has been configured to use, and then setting up the Ambari Server to use the newly created trust store. The steps are included below:

1. On the Ambari Server, create a new keystore that will contain the Ambari Server's HTTPS certificate.

```
keytool -import -file <path_to_the_Ambari_Server's_SSL_Certificate> -alias
ambari-server -keystore ambari-server-truststore
```

When prompted to 'Trust this certificate?' type "yes".

2. Configure the ambari-server to use this new trust store:

```
ambari-server setup-security
Using python /usr/bin/python2.6
Security setup options...
Choose one of the following options:
 [1] Enable HTTPS for Ambari server.
 [2] Encrypt passwords stored in ambari.properties file.
 [3] Setup Ambari kerberos JAAS configuration.
 [4] Setup truststore.
 [5] Import certificate to truststore.
Enter choice, (1-5): *4*
Do you want to configure a truststore [y/n] (y)? *y*
TrustStore type [jks/jceks/pkcs12] (jks): *jks*
Path to TrustStore file : *<path to the ambari-server-truststore keystore>*
Password for TrustStore:
Re-enter password:
Ambari Server 'setup-security' completed successfully.
```

3. Once configured, the Ambari Server must be restarted for the change to take effect.

ambari-server restart

3. Running Ambari Server Standalone

You can run one or more separate Ambari Server instances running in "standalone" mode. Running "standalone" Ambari Server instances is useful when users who will access views will not have (and should not) have access to that Ambari Server that is operating the cluster. As well, you can run one or more separate Ambari Server instances "standalone" for a scale-out approach to handling a large amount of users. See Reverse Proxy for more information.

Note

When running Ambari Server Standalone, and the cluster is being operated by an Ambari Server, you will have an option to configure that cluster as a Remote Cluster and then **use the Remote Cluster option** when configuring the view instance.

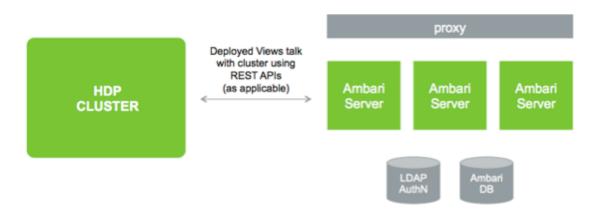

1. Prerequisites

There are several requirements that need to be considered when setting up multiple Ambari Server "standalone" instances:

- Ambari Server instances should be the same version.
- The Ambari Server instances should point to the same underlying database. Ensure that it is **not** the same database that is being used by an Operational Ambari Server managing the HDP cluster.
- Ambari database should be scaled and made highly-available, independent of Ambari Server.
- If using an external authentication source (such as LDAP or Active Directory), Ambari Server authentication should be configured the same for all Ambari Server instances.
- If the cluster you are accessing with Views is Kerberos-enabled, you need to configure Ambari and the Views for Kerberos.
- Run the multiple "standalone" Ambari Server instances behind a Reverse Proxy.

After your standalone Ambari Servers are setup and configured, you can configure the views to communicate with your HDP cluster.

2. Standalone Server Setup

Setting up a standalone Ambari Server instance is very similar to setting up an operational Ambari Server. Many of the steps are the same, with one key **exception: you do not install a cluster with a standalone Ambari Server**. A standalone Ambari Server does not manage a cluster and does not deploy or communicate with Ambari Agents. The standalone Ambari Server runs as web server instance, serving views for users.

Important

Refer to the Ambari Install Guide for the details steps for setting up an Ambari Server. For a standalone Ambari Server instance, you are not required to install a cluster.

Important

Refer to Managing Views in Hortonworks Data Platform Apache Ambari Administration for information on deploying and configuring Views.

The following table compares the high-level tasks required to setup an operational Ambari Server vs. a standalone Ambari Server.

	Operational Ambari Server	Standalone Ambari Server	
1	Install ambari -server package	Install ambari -server package	
2	Run ambari -server setup (DB, JDK)	Run ambari -server setup (DB, JDK)	
		Do not share the DB with an Operational Ambari Server.	
3	Configure external LDAP authentication	Configure external LDAP authentication	
4	Install Cluster	NA	
5	Deploy views	Deploy views	
6	Create + configure view instances	Create + configure view instances	
7		(Optional) Repeat for each Ambari Server instance	
8		(Optional) Set up proxy for Ambari Server instances	

	Operational Ambari Server	Standalone Ambari Server
9		(Optional) Set up SSL for Ambari

3. Reverse Proxy

If you require a larger number of users to access Ambari Views, it may be necessary to "scale-out" the Ambari Server by installing and running multiple Ambari Server standalone instances that host Ambari Views and run those instances behind a reverse proxy.

If a reverse proxy fronts the standalone Ambari Server instances, the only requirement is that the reverse proxy honors session affinity, meaning that once a session has been established the reverse proxy routes each subsequent request to the same Ambari server instance. Depending on the reverse proxy implementation, this can be accomplished in a number of different ways, including hashing client IP and using the JSESSIONID header.

Important

Using multiple Ambari Server instances and a reverse proxy in front of those instances is **not supported** for an operational Ambari Server. It is only supported for standalone Ambari Server instances (i.e. Ambari instances that are not managing a cluster).

4. Configuring Views for Kerberos

If the cluster your views will communicate with is Kerberos-enabled, you need to configure the Ambari Server instance(s) for Kerberos and be sure to configure the views to work with Kerberos.

Refer to the Set Up Kerberos for Ambari for the instructions on how to configure Ambari Server for Kerberos. Be sure to configure all standalone Ambari Server instances for Kerberos.

Important

Be sure to install the Kerberos client utilities on the Ambari Server so that Ambari can kinit.

RHEL/CentOS/Oracle Linux

yum install krb5-workstation

SLES

zypper install krb5-client

Ubuntu/Debian

apt-get install krb5-user krb5-config

Once your Ambari Server is setup for Kerberos, be sure to follow the specific instructions with each view on how to configure the view for Kerberos and the cluster for Kerberos access from the view. Also, if the view requires HDFS or WebHCat to be configured for a proxy user, **instead of using the ambari-server daemon user as the proxy user, you must user primary Kerberos principal**. For example, if you configure Ambari Server for Kerberos principal **ambari-server@EXAMPLE.COM**, this value would be **ambari-server**.

5. Technical Preview: Migrating Hue to Ambari Views

Because some users are using the open-source web interface Hue, rather than the Ambari Views Framework, to use Hortonworks Data Platform (HDP) components, Ambari 2.4 introduces a Technical Preview of the Hue-to-Views Migration tool, which is specifically designed to migrate existing Apache Hue artifacts to an Ambari view.

This chapter describes how to configure for, create, and use this Technical Preview tool:

- Requirements for Hue-to-Views Migration [9]
- Creating a Hue-to-Views instance [10]
- Example: Using the Hue-to-Views Migration Tool [13]

1. Requirements for Hue-to-Views Migration

Prerequisites

- Hue service must have a network connection to an Ambari Server serving the Hue-to-Views migration tool.
- Ambari Server must be enabled as a views server.
- Database access rights must be granted to the Hue back-end database (mysql, oracle, and postgresql).

Supported Artifacts and Expectations

The Hue-to-Views migration tool supports migrating the following artifacts:

Hive

- Saved Queries
- Query History

Pig

- Saved scripts
- Pig Jobs

Important

Scripts maintain the same status in the Ambari Views Framework as they had in Hue. The Hue-to-Views Migration tool does not validate scripts.

Some hive queries (mysql version 0.4.0) may fail to migrate, and cause the Hueto-Views migration to stop.

The Hue-to-Views migration tool does not support HA. You must provide the current, active namenode for the target cluster regarding the Webhdfs URI for Ambari.

2. Creating a Hue-to-Views instance

To create an instance of a Hue-to-Views view on the Ambari Dashboard, use Manage Ambari:

- 1. In Ambari Web, select admin > Manage Ambari.
- 2. On the Ambari Admin page, click Views.
- 3. In View Name, browse to HUETOAMBARI_MIGRATION and expand.
- 4. Click Create Instance

Roles	View Name Insta	inces
Go to Dashboard	SCAPACITY-SCHEDULER	1.0.0 (1)
Versions	> FILES	1.0.0 (1)
Remote Clusters	> HIVE	1.0.0 (0) , 1.5.0 (1)
	> HORTONWORKS_SMARTSENSE	1.3.0.0-22 (1)
III Views	✓ HUETOAMBARI_MIGRATION	1.0.0 (0)
Views		+ Create Instance
View URLs		

5. On Views/Create Instance, provide required values for the instance name, display name, and description.

Views / Create Instance

View	HUETOAMBARI_MIGRATION		
Version	1.0.0	\$	
Details			
	Instance Name*	HueToAmbari	
	Display Name*	HueToAmbari	
	Description*	example Hue-to-Ambari view instance	
		✓ Visible	

6. Provide required values for all Hue-to-Views migration settings.

Settings	
Hue Http URL	Enter Hue Server http URL
Hue Server hostname	Enter Hue Server Hostname
Ambari http URL	Enter Ambari Server http URL
Ambari Server hostname	Enter Ambari Server Hostname
Webhdfs URI(Hue)	Enter Webhdfs URI of Hue
Webhdfs URI(Ambari)	Enter Webhdfs URI of Ambari
Hue Database Driver	Enter Hue Database Driver
Hue JDBC URL	Enter Hue JDBC Url
Hue Database Username	Enter Username for Hue DB
Hue Database Password	Enter Password for Hue DB
Ambari Database Driver	Enter Ambari Database Driver
Ambari JDBC URL	Enter Ambari JDBC Url
Ambari Database Username	Enter Ambari DB Username
Ambari Database Password	Enter Ambari DB Password
Kerberos enabled on Ambari cluster?(y/n)	y/n
principal name (if kerberos is enabled)	Please enter the principal name is kerberos is enabled

7. Click Save.

The new, HUETOAMABARI view displays in the list of Ambari Views. To use the new view, click Go To Dashboard.

For example configuration settings and descritpions, see, Example: Using the Hue-to-Views Migration Tool.

3. Example: Using the Hue-to-Views Migration Tool

In a test environment, configure an example, 3-node cluster using the following settings:

- Hue Server url : c6401.ambari.apache.org
- Hue NameNode URI: c6402.ambari.apache.org
- NameNode port: 50070
- Hue Database Name(mysql): Huedb
- Hue Database username(mysql): hue
- Hue Database Password(mysql): hue
- Ambari Hostname: c6402.ambari.apache.org
- Ambari Database Name (postgresql): ambari
- Ambari Database username (postgresql): ambari
- Ambari Database Password (postgresql): bigdata

Property	Description	Syntax	Example
Hue Http URL	Https url where Hue server is located	<hue http="" url=""></hue>	http://c6401.ambari.apache.org:8000/
Hue Server hostname	hostname on which Hue runs (the host from which you migrate data)	<hue hostname=""></hue>	c6401.ambari.apache.org
Ambari http URL	http url of the Ambari Server	<ambari http="" url=""></ambari>	http://c6402.ambari.apache.org:8080/
Ambari Server hostname	hostname of the Ambari server	<ambari hostname=""></ambari>	c6402.ambari.apache.org
Webhdfs URI (Hue)	Namenode URI of Hue	webhdfs:// <hostname>:50070</hostname>	webhdfs:// c6402.ambari.apache.org:50070
Webhdfs URI (Ambari)	NameNode URI of Ambari	webhdfs:// <hostname>:50070</hostname>	webhdfs:// c6402.ambari.apache.org:50070
Hue Database Driver	JDBC Driver to access Hue DB	<db driver=""></db>	com.mysql.jdbc.Driver
Hue JDBC URL	JDBC Url to access Hue DB	jdbc: <dbtype>:// <hostname>/<db name></db </hostname></dbtype>	jdbc:mysql://c6401.ambari.apache.org/ huedb
Hue Database Username	Hue Database Username	<db username=""></db>	hue
Hue Database Password	Hue Database Password	<db password=""></db>	hue
Ambari Database Driver	JDBC Driver to access Ambari DB	<db driver=""></db>	org.postgresql.Driver

Property	Description	Syntax	Example
Ambari JDBC URL	JDBC Url to access Ambari DB	jdbc: <dbtype>:// <hostname>/<db name></db </hostname></dbtype>	jdbc:postgresql:// c6402.ambari.apache.org:5432/ambari
Ambari Database Username	database username for Ambari	<db username=""></db>	ambari
Ambari Database Password	database password for the Ambari database	<db password=""></db>	bigdata
Kerberos enabled on Ambari cluster? (y/n)	(y/n) for Kerberos	<y n=""></y>	n
Principal name (if Kerberos enabled)	If Kerberos is enabled, you must provide Principal Name	<principal username></principal 	ambari-cl1

For more information about how to obtain driver class information, see https://docs.oracle.com/javase/7/docs/api/java/sql/DriverManager.html.

6. Using the YARN Queue Manager View

The Yarn Capacity Scheduler allows for multiple tenants in an HDP cluster to share compute resources according to configurable workload management policies.

The YARN Queue Manager View is designed to help hadoop operators configure these policies for YARN. In the View, operators can create hierarchical queues and tune configurations for each queue to define an overall workload management policy for the cluster.

In this section:

- Configuring your Cluster for the Capacity Scheduler View [15]
- Creating a Capacity Scheduler View Instance [15]
- Using the YARN Queue Manager View [22]
- Troubleshooting [30]

1. Configuring your Cluster for the Capacity Scheduler View

The Capacity Scheduler View requires that the cluster is managed by Ambari – the view utilizes the Ambari Server API.

2. Creating a Capacity Scheduler View Instance

When you deploy a cluster using Ambari, a Capacity Scheduler View instance is automatically created. If you do not need to reconfigure the Ambari-created cluster, proceed to the next section, Using the YARN Queue Manager View.

If you have deployed your cluster manually, or if you need to re-configure the Ambaricreated YARN Queue Manager View, you can use the information in this section to create and configure a view instance.

Use the following steps to set up a Capacity Scheduler / YARN Queue Manager view instance.

Other Bookmar

	> TEZ	0.7.0.2.3.0.0-812 (1)	

4. In the Details box on the Create Instance page, type in an instance name, display name, and a description for the view.

Note

The instance name cannot contain spaces or special characters.

- 5. In the Cluster Configuration box on the Create Instance page, configure the view to communicate with the HDP cluster.
 - For HDP clusters that are local (managed by the local Ambari Server), select the Local Ambari Managed Cluster option, then select the local cluster name.

- To configure the view to work with HDP clusters that are remote (not part of this Ambari Server instance), select the **Custom** option, then specify the remote Ambari cluster API URL and the Ambari cluster user name and password.
- 6. Click **Save** at the bottom of the page.

3. Using the YARN Queue Manager View

The YARN Queue Manager View is designed to help hadoop operators configure workload management policies for YARN. In the YARN Queue Manager View, operators can create hierarchical queues and tune configurations for each queue to define an overall workload management policy for the cluster.

3.1. Setting up Queues

Use the following steps to set up Capacity Scheduler queues on a view instance.

1. On the YARN Queue Manager view instance configuration page, click **Add Queue**. The queue will be added under the top level, or "root" queue. A "default" queue already exists under the root queue.

Note

To return to a previously created YARN Queue Manager view instance, click **Views** on the Manage Ambari page, then click **CAPACITY-SCHEDULER**. Click the applicable YARN Queue Manager view instance, then click **Go to instance** at the top of the page.

3.2. Configuring Queues

To configure a queue, click the queue name, then set the following queue parameters:

Note

Hold the cursor over a parameter name to display a description of the parameter.

Capacity

- Capacity The percentage of cluster resources available to the queue. For a sub-queue, the percentage of parent queue resources.
- Max Capacity The maximum percentage of cluster resources available to the queue. Setting this value tends to restrict elasticity, as the queue will be unable to utilize idle cluster resources beyond this setting.
- Enable Node Labels Select this check box to enable node labels for the queue.

Access Control and Status

• State – Running is the default state. Setting this to Stopped lets you gracefully drain the queue of jobs (for example, before deleting a queue).

- Administer Queue Click **Custom** to restrict administration of the queue to specific users and groups.
- Submit Applications Click **Custom** to restrict the ability to run applications in the queue to specific users and groups.

Resources

- User Limit Factor The default value of "1" means that any single user in the queue can at maximum only occupy the queue's configured capacity. This prevents users in a single queue from monopolizing resources across all queues in a cluster. Setting the value to "2" would restrict the queue's users to twice the queue's configured capacity. Setting it to a value of 0.5 would restrict any user from using resources beyond half of the queue capacity.
- Minimum User Limit This property can be used to set the minimum percentage of resources allocated to each queue user. For example, to enable equal sharing of the queue capacity among five users, you would set this property to 20%.
- Maximum Applications This setting enables you to override the Scheduler Maximum Applications setting (described in Configuring Cluster Scheduler Settings). The default setting is Inherited (no override).
- Maximum AM Resource This setting enables you to override the Scheduler Maximum AM Resource setting (described in Configuring Cluster Scheduler Settings). The default setting is Inherited (no override).
- Ordering Policy You can specify FIFO (First In, First Out) or fair (Fair Scheduler: applications get a fair share of capacity regardless of the order in which they were submitted).

The following image shows the example "Engineering" queue with these settings specified:

+ Add Q	Ac Ac	tions +	Engineerin	g 🕜			>
root (1	00%)	~	root.Engineering				
d	efault (0%)	~	Capacity		Level T	otal 10	9%
B	ngineering (80%)	v	Engineering				P Enable node labels
= M	arkerting (30%)	~	Capacity: 60	%	- Ma	x Capacity: 60 %	
• S	upport (10%)	× .					Node Labels Access
Scheduler		~			♥ Show Peer	Level Queues	
		0	Access Contro	I and Status		Resources	
Applic			State	Running Stopped		User Limit Factor	1

Node L	Delay 40		Users	bsmith.diones	40	Maximum Applications	Inherited
Cale	ulator org.apache.hado	100 VWT	Ciaria -			Maximum AM Resource	Inha 56
			Groups	project_management	삼	Maximum AM Hesource	1111 20
			Submit Applications	Anyone Custom		Ordering policy	fifo \$
Versions					_		
vil Current	a minute ago	load	Users	bsmith,djones	<u> </u>		
15	16 minutes ago	load	Groups	project_management	*		
-	3 hours ago	load					
68	4 hours ago	load					
*2	4 hours ago	load					

3.3. Configuring Cluster Scheduler Settings

You can use the Scheduler box to set global capacity scheduler settings that apply to all queues.

+ Add Queue 2 Ad	ions -	Engineering 2 root.Engineering	×
default (0%)	~	Capacity	Level Total 100%
Engineering (80%) Markerting (30%) Support (10%)	 	Engineering Capacity: 60 55	Max Capacity: 100 %
Scheduler	~		Show Peer Level Queues
Maximum 10000 (1) Applications 20 % Node Locality 40 Delay Calculator org.apacha.hadoog	xyarr	Access Control and Status State Running Administer Guess Users Dentift_djones Groups project_management Submit Anyone Custom	Resources User Limit Factor 1 Minimum User Limit 20 Maximum Applications Inherted Maximum AM Resource Inherted Ordering policy %0

The following Scheduler global parameters are available:

- Maximum Applications To avoid system-thrash due to an unmanageable load caused either by malicious users, or accidentally the Capacity Scheduler enables you to place a static, configurable limit on the total number of concurrently active (both running and pending) applications at any one time. This property is used to set this limit, with a default value of 10,000.
- Maximum AM Resource The limit for running applications in any specific queue is a fraction of this total limit, proportional to its capacity. This is a hard limit, which means that once this limit is reached for a queue, any new applications submitted to that queue will be rejected, and clients will have to wait and retry later.
- Node Locality Delay The number of missed scheduling cycles after which the scheduler attempts to schedule rack-local containers.
- Calculator The method by which the scheduler calculates resource capacity across resource types.

3.4. Applying the Configuration Changes

You can use the Actions menu to apply configuration changes made to the queue hierarchy.

Depending on the configuration changes made, the Actions menu will guide you to the options available to apply the changes.

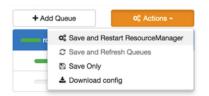

For changes that are not valid and cannot be applied, the **Actions** button will turn red, and the menu will not appear.

+ Add Queue	C Actions -
root (100%)	~
default (62%)	A 🧷
Scheduler	×

For configuration changes that can be applied dynamically (without restarting the YARN ResourceManager), the Actions Menu will guide you to **Save and Refresh Queues**.

For configuration changes that require a restart of the YARN ResourceManager, the Actions Menu will guide you to **Save and Restart ResourceManager**.

4. Troubleshooting

If you encounter an issue where the configurations cannot be applied from the View, you should go to the local Ambari Server instance managing the cluster and directly edit the Capacity Scheduler configuration from the YARN configuration page.

In the local Ambari instance, navigate to **Services > YARN**, then select the **Configs** tab. On the **Advanced** tab, expand the Scheduler section.

yarn.resourcemanager.	org.a pache.hadoop.yarn.server.resourcemanager.scheduler.capacity.CapacityScheduler.capacity.capacityScheduler.capacity.capacityScheduler.capacity.capacityScheduler.capacity.capacityScheduler.capacity.capacityScheduler.capacity.capacityScheduler.capacityScheduler.capacity.capacityScheduler.capacityScheduler.capacity.capacityScheduler.capacity.capacityScheduler.capacity.capacityScheduler.capacity.capacity.capacityScheduler.capacity.capacit		0	C
scheduler.class				
Capacity Scheduler	yarn.scheduler.capacity.maximum-am-resource-percent=0.2			
	yarn.scheduler.capacity.maximum-applications=10000			
	yarn.scheduler.capacity.node-locality-delay=40			
	yarn.scheduler.capacity.queue-mappings-override.enable=false			
	yarn.scheduler.capacity.root.accessible-node-labels=*	•	C	
	yarn.scheduler.capacity.root.acl_administer_queue=*	×	0	
	yarn.scheduler.capacity.root.capacity=100			
	yarn.scheduler.capacity.root.default.acl_submit_applications=*			
	yarn.scheduler.capacity.root.default.capacity=100			
	yarn.scheduler.capacity.root.default.maximum-capacity=100			

Here you will be able to edit the underlying configurations for the YARN Queue Manager and fix any issues you may encounter.

7. Using the Files View

The **Files View** provides a convenient way to access HDFS through a web-based interface. The Files View supports:

- Moving Files/ Folders within HDFS
- Copying Files/Folders within HDFS
- Uploading files from a local system
- Modifying permissions of files and folders

This document provides information on how to configure a Files View instance and use the File browser UI to access HDFS.

- Configuring Your Cluster [31]
- Creating and Configuring a Files View Instance [32]
- Troubleshooting [34]

Important

It is critical that you prepare your Ambari Server for hosting views. It is strongly recommended you increase the amount of memory available to your Ambari Server, and that you run additional "standalone" Ambari Servers to host the views. See Preparing Ambari Server for Views and Running Ambari Server Standalone for more information.

1. Configuring Your Cluster

For the Files View to access HDFS, the Ambari Server daemon hosting the view needs to act as the proxy user for HDFS. This allows Ambari to submit requests to HDFS on behalf of the users using the Files View.

Note

If you are running views in an operational Ambari server (one that is operating the cluster) Ambari does this setup by default. You should verify that the setup described in the following subsections has been completed. If you are running views on a standalone server, you must setup proxy user settings manually, using the following instructions.

To set up an HDFS proxy user for the Ambari Server daemon account, you need to configure the proxy user in the HDFS configuration. This configuration is determined by the account name the **ambari-server** daemon is running as. For example, if your ambari-server is running as **root**, you set up an HDFS proxy user for **root** with the following:

- 1. In Ambari Web, browse to Services > HDFS > Configs.
- 2. Under the Advanced tab, navigate to the Custom core-site section.
- 3. Click Add Property... to add the following custom properties:

```
hadoop.proxyuser.root.groups="users"
hadoop.proxyuser.root.hosts=ambari-server.hostname
```

Notice the **ambari-server** daemon account name **root** is part of the property name. Be sure to modify this property name for the account name you are running the ambariserver as. For example, if you were running **ambari-server** daemon under an account name of **ambariusr**, you would use the following properties instead:

```
hadoop.proxyuser.ambariusr.groups="users"
hadoop.proxyuser.ambariusr.hosts=ambari-server.hostname
```

Similarly, if you have configured Ambari Server for Kerberos, be sure to modify this property name for the primary Kerberos principal user. For example, if ambari-server is setup for Kerberos using principal **ambari-server@EXAMPLE.COM**, you would use the following properties instead:

```
hadoop.proxyuser.ambari-server.groups="users"
hadoop.proxyuser.ambari-server.hosts=ambari-server.hostname
```

4. Save the configuration change and restart the required components as indicated by Ambari. In order to use the Hive View, you should also restart HiveServer2.

2. Creating and Configuring a Files View Instance

- 1. Browse to the Ambari Administration interface.
- 2. Click Views, expand the Files View, and click Create Instance.
- 3. Enter the following View instance Details:

Property	Description	Value FILES_1	
Instance Name	This is the Files view instance name. This value should be unique for all Files view instances you create. This value cannot contain spaces and is required.		
Display Name	This is the name of the view link displayed to the user in Ambari Web.	MyFiles	
Description	This is the description of the view Bro displayed to the user in Ambari Web. file direction		
Visible	This checkbox determines whether the view is displayed to users in Ambari Web.	Visible or Not Visible	

- 4. The **Settings** and **Cluster Configuration** options depend on a few cluster & deployment factors in your environment:
 - Is your cluster Kerberos-enabled?
 - Is NameNode HA configured?
 - Is your **Files View** instance being configured in an **Operational** Ambari Server or a **Standalone** Ambari Server?

Refer to the following table on the instructions to complete the **Files View** configuration:

Kerberos Enabled	NameNode HA Enabled	Operational Ambari Server	Standalone Ambari Server
		see note #1:	see note #2:
No	No	Settings: defaults	Settings: defaults
No	Yes	Cluster Configuration: Local	Cluster Configuration: Custom
Yes	No	Settings : Kerberos	
		Cluster Configuration : Custom	
Yes	Yes	Settings: Kerberos	
		Cluster Configuration: Custom	

Note

#1: The Local Ambari Managed Cluster Configuration option is enabled in the Ambari Administration Interface only if you are managing a cluster in an Operational Ambari Server.

Note

#2: See Running Ambari Standalone for more information.

2.1. Kerberos Settings

You must first set up Kerberos for Ambari by configuring the Ambari Server daemon with a Kerberos principal and keytab. Refer to Configuring Views for Kerberos for instructions. After you have set up Kerberos for Ambari, in the Settings section of the Files View, enter the following:

Property	Description	Example Value
WebHDFS Username	This is the username the view will access HDFS as. Leave this default value intact to represent the authenticated view user.	\${username}
WebHDFS Authorization	This is the semicolon-separated authentication configuration for WebHDFS access.	auth=KERBEROS;proxyuser=ambari-server Note
		This property is only needed if the view is Custom Configured or Ambari Server is Kerberized before 2.4.0.

Note

With a Kerberos setup, the proxy user setting should be the primary value of the Kerberos principal for Ambari Server. For example, if you configured Ambari Server for Kerberos principal **ambari-server@EXAMPLE.COM**, this value would be **ambari-server**. Refer to **Configuring Views for Kerberos** for more information..

2.2. Cluster Configuration: Local

The Local Ambari Managed Cluster Configuration option is enabled in the Ambari Administration Interface if you are managing a cluster with Ambari. When enabled, you can choose this option and Ambari will automatically configure the view based on how the cluster is configured.

When you configure the view using the Local option, the Files View will communicate with HDFS based on the **fs.defaultFS** property (for example: hdfs://namenode:8020). The View will also determine if NameNode HA is configured and adjust accordingly.

2.3. Cluster Configuration: Custom

These properties are required if using Custom configuration.

Required Properties	Description	Example Value
WebHDFS FileSystem URI	The WebHDFS FileSystem URI in the format webhdfs:// <host>:<http_port></http_port></host>	webhdfs://namenode:50070

These properties are required if your cluster is configured for NameNode HA.

Property	Description	Example Value
Logical name of the NameNode cluster	Comma-separated list of nameservices.	hdfs-site/dfs.nameservices
Namenoue cluster		For example:
		nameservice
List of NameNodes	Comma-separated list of NameNodes for a given nameservice.	hdfs-site/dfs.ha.namenodes
	a given nameservice.	For example:
		namenode1,namenode2
First NameNode RPC Address	RPC address for first name node.	hdfs-site/dfs.namenode.rpc-address. [nameservice].[namenode1]
Second NameNode RPC Address	RPC address for second NameNode.	hdfs-site/dfs.namenode.rpc-address. [nameservice].[namenode2]
First NameNode HTTP (WebHDFS) Address	WebHDFS address for first NameNode.	hdfs-site/dfs.namenode.http-address. [nameservice].[namenode1]
Second NameNode HTTP (WebHDFS) Address	WebHDFS address for second NameNode.	hdfs-site/dfs.namenode.http-address. [nameservice].[namenode2]
Failover Proxy Provider	The Java class that HDFS clients use to contact the Active NameNode.	hdfs-site/ dfs.client.failover.proxy.provider. [nameservice]

2.4. Troubleshooting

Error	Solution
500 Usernames not matched: name=root != expected=ambari- server	If your cluster is configured for Kerberos, double-check WebHDFS Authorization setting and confirm the "proxyuser=" part of the string is set to the Ambari Server principal name.
	For example:
	auth=KERBEROS; proxyuser=ambari-server
	Refer to Kerberos Settings.
500 User: ambari-server is not allowed to impersonate admin	HDFS has not been configured for Ambari as a proxy user.
	Refer to Configuring Your Cluster.
500 SIMPLE authentication is not enabled. Available:[TOKEN, KERBEROS]	If your cluster is configured for Kerberos, you cannot use the Local Cluster Configuration option. You must use the

Error	Solution
	Custom Cluster Configuration option and enter the WebHDFS FileSystem URI.
	For example:
	webhdfs://namenode:50070
	Refer to Cluster Configuration: Custom

8. Using the Falcon View

Apache Falcon solves enterprise challenges related to Hadoop data replication, business continuity, and lineage tracing by deploying a framework for data management and processing. The Falcon framework can also leverage other HDP components, such as Apache Pig, Apache Hadoop Distributed File System (HDFS), Apache Sqoop, Apache Hive, Apache Spark, and Apache Oozie. Falcon enables this simplified management by providing a framework to define and manage backup, replication, and data transfer.

Hadoop administrators can use the **Falcon View** to centrally define, schedule, and monitor data management policies. **Falcon** uses those definitions to auto-generate workflows in Apache Oozie.

This chapter describes the following:

- Section 1, "Configuring Your Cluster" [36]
- Section 2, "Installing and Configuring the Falcon View" [37]
- Section 3, "Accessing the Falcon Documentation" [41]

1. Configuring Your Cluster

For the Falcon View to access HDFS, the Ambari Server daemon hosting the view needs to act as the proxy user for HDFS. This allows Ambari to submit requests to HDFS on behalf of the users using the Falcon View. This is critical since the Falcon View stores metadata about the user Falcon entity definitions. This also means users who access the Falcon View must have a user directory setup in HDFS.

1.1. Setup HDFS Proxy User

To set up an HDFS proxy user for the Ambari Server daemon account, you need to configure the proxy user in the HDFS configuration. This configuration is determined by the account name the **ambari-server** daemon is running as. For example, if your ambari-server is running as **root**, you set up an HDFS proxy user for **root** with the following:

- 1. In Ambari Web, browse to Services > HDFS > Configs.
- 2. Under the Advanced tab, navigate to the Custom core-site section.
- 3. Click Add Property... to add the following custom properties:

```
hadoop.proxyuser.root.groups="users"
hadoop.proxyuser.root.hosts=ambari-server.hostname
```

Notice the **ambari-server** daemon account name root is part of the property name. Be sure to modify this property name for the account name you are running the ambari-server as. For example, if you were running **ambari-server** daemon under an account name of **ambariusr**, you would use the following properties instead:

```
hadoop.proxyuser.ambariusr.groups="users"
hadoop.proxyuser.ambariusr.hosts=ambari-server.hostname
```

Similarly, if you have configured Ambari Server for Kerberos, be sure to modify this property name for the **primary Kerberos principal** user. For example, if ambari-server is setup for Kerberos using principal **ambari-server@EXAMPLE.COM**, you would use the following properties instead:

```
hadoop.proxyuser.ambari-server.groups="users"
hadoop.proxyuser.ambari-server.hosts=ambari-server.hostname
```

4. Save the configuration change and restart the required components as indicated by Ambari.

1.2. Setup HDFS User Directory

The Falcon View stores user metadata in HDFS. By default, the location in HDFS for this metadata is /user/\${username} where \${username} is the username of the currently logged in user that is accessing the Falcon View.

Important

Since many users leverage the default Ambari admin user for getting started with Ambari, the /user/admin folder needs to be created in HDFS. Therefore, be sure to create the admin user directory in HDFS using these instructions prior to using the view.

To create user directories in HDFS, do the following for each user you plan to have use the Hive View.

- 1. Connect to a host in the cluster that includes the HDFS client.
- 2. Switch to the hdfs system account user.

su - hdfs

3. Using the HDFS client, make an HDFS directory for the user. For example, if your username is admin, you would create the following directory.

```
hadoop fs -mkdir /user/admin
```

4. Set the ownership on the newly created directory. For example, if your username is admin, you would make that user the directory owner.

```
hadoop fs -chown admin:hadoop /user/admin
```

2. Installing and Configuring the Falcon View

You must manually copy the .jar file for the Falcon View, then configure Ambari to access the View. You can install the Falcon View in a secure or an unsecure cluster. If using a secure cluster, Ambari and Falcon must be properly configured with Kerberos.

Prerequisites

• Apache Falcon must have been installed and configured, and be deployed in Ambari.

For an Ambari-managed installation, Falcon is included as a default service. To deploy the Falcon service, refer to Adding a Service to your Hadoop cluster.

For manual (non-Ambari) installation and setup of Falcon, refer to Installing Apache Falcon, then Adding a Service to your Hadoop cluster.

• The users and groups for Falcon must exist in Ambari prior to installing the Falcon View.

Refer to Managing Users and Groups.

• Falcon must have been configured as a proxy super user in the <code>oozie-site</code> properties and in the HDFS <code>core-site</code> properties.

Steps

- 1. Copy the Falcon View falcon-ambari-view.jar file from the Falcon server / webapp directory to the Ambari server /views directory.
 - If the Falcon and Ambari servers are on the same host, use the copy command:

```
cp /usr/hdp/current/falcon-server/server/webapp/falcon-ambari-view.jar /
var/lib/ambari-server/resources/views/
```

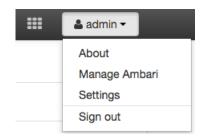

• If the Falcon server is on a remote host, use the secure copy command for your operating system.

A key pair might be required. See your operating system documentation for more information about remote copies.

2. Restart the Ambari server.

[root@DataMovementDocs-1 ~]# ambari-server restart

3. In Ambari, navigate to *user_name* > Manage Ambari.

- 4. Under Deploy Views, click Views, then click Falcon > Create Instance in the Views list.
- 5. Provide the required Details information.

Instance Name: 250 characters, no spaces, no special characters Display Name: 250 characters, including spaces; no special characters; can be the same as the Instance Name

Description: 140 characters max, including spaces; special characters allowed

Note

If you enter more than the allowed number of characters, you might see the error message Cannot create instance: Server Error.

6. Select a cluster configuration.

The Local and Remote fields populate with the names of available clusters. The authentication type for the cluster is automatically recognized.

To use a custom cluster location, enter the Falcon service URI and authentication type of simple or kerberos.

7. Click Save.

The Permissions section displays at the bottom of the Views page.

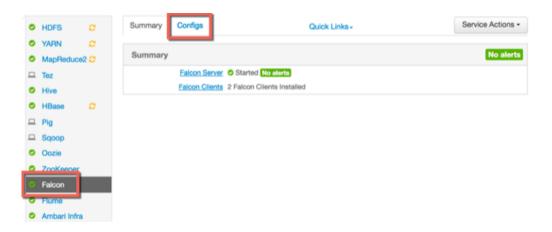

- 8. (Optional) Set the permissions for access to the view.
- 9. Hover over the Views icon to verify that your Falcon View is available in the menu.

Note

Do *not* click on the Falcon link yet. You must make additional configuration changes before you can access the Falcon View.

10.Click the Ambari icon to return to the Dashboard window, then click the **Falcon** service and the **Configs** tab.

11Scroll to the Falcon startup.properties section, locate the *.application.services field, and enter the following services immediately above the line org.apache.falcon.metadata.MetadataMappingService:

org.apache.falcon.service.GroupsService, \

org.apache.falcon.service.ProxyUserService,

12Add the proxy user for hosts and groups in the **Custom falcon-runtime.properties** section.

The proxy user is the user that the Falcon process runs as, typically Falcon.

- a. Click Add Property.
- b. Add the following key/value pairs.

Substitute *#USER#* with the proxy user configured for the Ambari server.

• Key=*.falcon.service.ProxyUserService.proxyuser.#USER#.hosts, Value=*

These are the hosts from which *#USER#* can impersonate other users.

• Key=*.falcon.service.ProxyUserService.proxyuser.#USER#.groups, Value=*

These are the groups that the users being impersonated must belong to.

Example 8.1. Substitute #USER#

In the key/value pairs above, if the #USER# is "falcon", enter
*.falcon.service.ProxyUserService.proxyuser.falcon.hosts.

The wildcard value=* (asterisk) is used to allow impersonation from any host or of any user. If you don't use the wildcard character, enter the appropriate host or group values.

Add Pro	perty x
Туре	falcon-runtime.properties.xml
Key	*.falcon.service.ProxyUserService.proxyuser.falcon.groups
Value	•
	4
	Cancel

13.Click **Save** on the information bar at the top of the Configs page.

<>	V18 admin 8 hours ago HDP-2.5	V17 admin 8 hours ago HDP-2.5	V16 admin 9 hours ago HDP-2.5	9 hours ago HDP-2.5	V14 admin 9 hours ago HDP-2.5	V13 about	admin t a day ago HDP-2.5
X - V18 v18 Discard Save					Save		
✓ Falcon Server							

If you try to leave the page without clicking Save, you see a Warning message. Click Save in the Warning dialog box.

- A Restart Required message displays at the top of the Falcon Configs page.
- 14.Click Restart > Restart All Affected to restart the Falcon services.
- 15.When the restart completes, verify that you can access the Falcon View by clicking Falcon in the Views menu.

3. Accessing the Falcon Documentation

You can access the Falcon documentation in the Data Movement and Integration guide on the Hortonworks documentation website.

9. Using the Hive View

Hive is a data warehouse infrastructure built on top of Hadoop. It provides tools to enable data ETL, a mechanism to put structures on the data, and the capability to query and analyze large data sets that are stored in Hadoop. The **Hive View** is designed to help you author, execute, understand, and debug Hive queries.

This chapter explains:

- Upgrading Your Hive View [43]
- Configuring Your Cluster [44]
- Creating the Hive View Instance [45]
- Using the Hive View [51]
- Upload Table tab [59]
- Troubleshooting [61]

Important

The Tez View integrates with the Hive View, especially for debugging and analyzing Hive queries. Please install the Tez View when you install the Hive View. See Using the Tez View for more information.

Important

It is critical that you prepare your Ambari Server for hosting views. It is strongly recommended you increase the amount of memory available to your Ambari Server, and that you run additional "standalone" Ambari Servers to host the views. See Preparing Ambari Server for Views and Running Ambari Server Standalone for more information.

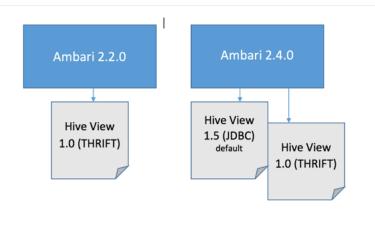

Hive Views

With the release of Apache Ambari 2.4.0, two Hive views install as part of your Hortonworks Data Platform distribution:

Hive View 1.0 - which works with Thift Java API

Hive View 1.5 - which works with the JDBC client

Previously, HDP only installed Hive View 1.0. Hive View 1.5 is now the default when you create a new view.

You can run both views simultaneously, use only one of the views, or upgrade your data from the older view to the newer view. Hortonworks recommends, for enhanced security and because of the future deprecation of Hive View 1.0, that you upgrade and migrate your data from the Hive View 1.0 to the Hive View 1.5.

1. Upgrading Your Hive View

If you are upgrading from Apache Ambari 2.2.0 to Apache Ambari 2.4.0 and want to upgrade and migrate the data and queries in your Hive Views, you will need to create a new instance of the Hive View and then migrate your queries.

Migrating your queries into the new view

Create a new Hive View 1.5 instance and then you will migrate the saved queries from the Hive View 1.0 instance to the new instance. To do that, run the following curl command.

```
curl -v -u admin:admin -X PUT -H X-Requested-By:1 http://<host/
ip ambari server>:8080/api/v1/views/<view name>/versions/<version
of target view>/instances/<instance name of target view>/
migrate/<version of source view>/<instance name of source view>
```

For information on where to get the specific parameters listed in the curl command, refer to the following figure:

Views / Hiv	ve View 🗠	to instance	
View Version	HIVE		<view name=""> </view>
Details			
Inst	ance Name	AUTO_HIVE_INSTANCE	<pre> <instance name="" of="" view=""></instance></pre>
Dis	splay Name	Hive View	
	Description	This is hive view	
	Short URL	Create New URL	
		S Visible	

2. Configuring Your Cluster

For the Hive View to access HDFS, the Ambari Server daemon hosting the view needs to act as the proxy user for HDFS. This allows Ambari to submit requests to HDFS on behalf of the users using the Hive View. This is critical since the Hive View will store metadata about their user Hive queries in HDFS. This also means users that will access the Hive View must have a user directory setup in HDFS.

Note

If you are running views in an operational Ambari server (one that is operating the cluster) Ambari does this setup by default. You should verify that the setup described in the following subsections has been completed. If you are running views on a standalone server, you must setup proxy user settings manually, using the following instructions.

- Setup HDFS Proxy User [44]
- Setup HDFS User Directory [45]

2.1. Setup HDFS Proxy User

To set up an HDFS proxy user for the Ambari Server daemon account, you need to configure the proxy user in the HDFS configuration. This configuration is determined by the account name the **ambari-server** daemon is running as. For example, if your ambari-server is running as **root**, you set up an HDFS proxy user for **root** with the following:

- 1. In Ambari Web, browse to Services > HDFS > Configs.
- 2. Under the Advanced tab, navigate to the Custom core-site section.
- 3. Click Add Property... to add the following custom properties:

```
hadoop.proxyuser.root.groups="users"
hadoop.proxyuser.root.hosts=ambari-server.hostname
```

Notice the **ambari-server** daemon account name root is part of the property name. Be sure to modify this property name for the account name you are running the ambari-

server as. For example, if you were running **ambari-server** daemon under an account name of **ambariusr**, you would use the following properties instead:

```
hadoop.proxyuser.ambariusr.groups="users"
hadoop.proxyuser.ambariusr.hosts=ambari-server.hostname
```

Similarly, if you have configured Ambari Server for Kerberos, be sure to modify this property name for the **primary Kerberos principal** user. For example, if ambari-server is setup for Kerberos using principal **ambari-server@EXAMPLE.COM**, you would use the following properties instead:

```
hadoop.proxyuser.ambari-server.groups="users"
hadoop.proxyuser.ambari-server.hosts=ambari-server.hostname
```

4. Save the configuration change and restart the required components as indicated by Ambari.

2.2. Setup HDFS User Directory

The Hive View stores user metadata in HDFS. By default, the location in HDFS for this metadata is /user/\${username} where \${username} is the username of the currently logged in user that is accessing the Hive View.

Important

Since many users leverage the default Ambari admin user for getting started with Ambari, the /user/admin folder needs to be created in HDFS. Therefore, be sure to create the admin user directory in HDFS using these instructions prior to using the view.

To create user directories in HDFS, do the following for each user you plan to have use the Hive View.

- 1. Connect to a host in the cluster that includes the HDFS client.
- 2. Switch to the hdfs system account user.

su - hdfs

3. Using the HDFS client, make an HDFS directory for the user. For example, if your username is admin, you would create the following directory.

```
hadoop fs -mkdir /user/admin
```

4. Set the ownership on the newly created directory. For example, if your username is admin, you would make that user the directory owner.

```
hadoop fs -chown admin:hadoop /user/admin
```

3. Creating the Hive View Instance

- 1. Click Manage Ambari to open the Ambari Administration user interface.
- 2. Click Views, expand the Hive View, and click Create Instance.

- 3. On the Create Instance page, select the **Version**. If multiple Hive View jars are present, choose one.
- 4. Enter the following view instance Details:

Table 9.1. Hive View Instance Details

Property	Description	Example Value
Instance Name	This is the Hive view instance name. This value should be unique for all Hive view instances you create. This value cannot contain spaces and is required.	AUTO_HIVE_INSTANCE
Display Name	This is the name of the view link displayed to the user in Ambari Web.	Hive View
Description	This is the description of the view displayed to the user in Ambari Web.	Auto-created when the Hive service is deployed.
Visible	This checkbox determines whether the view is displayed to users in Ambari Web.	Visible or Not Visible

- 5. The **Settings** and **Cluster Configuration** options depend on a few cluster and deployment factors in your environment. Typically, you can accept the default **Settings** unless you are using the Hive View with a Kerberos-enabled cluster. Refer to Settings and Cluster Configuration for more information.
- 6. Click Save.

3.1. Settings and Cluster Configuration

Ambari configures Hive View settings automatically when you choose to add the Hive service. The default Hive View settings are shown in the following figure:

Figure 9.1. Default Hive View Settings

Settings	/ Ec
Hive Session Parameters	transportMode=http;httpPath=cliservice
WebHDFS Username	\${username}
WebHDFS Authentication	auth=SIMPLE
Instance name of Tez view	
Scripts HDFS Directory*	/user/\${username}/hive/scripts
Jobs HDFS Directory*	/user/\${username}/hive/jobs
Default script settings file*	/user/\${username}/.\${instanceName}.defaultSettings

The default Hive View cluster configuration is shown in the following figure:

YARN ResourceManager URL*	http://yarn.resourcemanager.address:8088	

Figure 9.2. Default Hive View Cluster Configuration

If required for migrating view instances, the following table describes how to locate cluster configuration settings using Ambari.

Table 9.2. Finding Cluster Configuration Values for the Hive View usingAmbari

Property	Value		
HiveServer2 JDBC URL	Click Hive > Summary to view the URL, diplayed at the bottom of the Summary list.		
For secured clusters, see Kerberos Setup for Hive Views	For example:		
	jdbc:hive2:// c6403.ambari.apache.org:2181,c6401.ambari.apache.org:2181,c640		
live Metastore directory	Click Hive > Configs > Advanced > General. For example, /apps/hive/ warehouse		
NebHDFS FileSystem URI*	Click HDFS > Configs > Advanced >Advanced hdfs-site For example dfs.nameserviceid.http-address		
	<pre>For HA: Click HDFS > Configs > Advanced > Advanced hdfs-site > dfs.nameservice.id. When you enter the value in the view definition, pre-pend "webhdfs://" to the value you find in the advanced HDFS configuration settings. For example, webhdfs://c6401.ambari.apache.org:50070 or webhdfs:// nameserviceid</pre>		
Logical Name of the NameNode cluster			
List of NameNodes			
First NameNode RPC Address	Click HDFS > Configs > Advanced > Advanced hdfs-site > dfs.namenode.rpc- address.		
	See the first address in the list. For example, c6401.ambari.apache.org		
Second NameNode RPC Address	Click HDFS > Configs > Advanced > Advanced hdfs-site > dfs.namenode.rpc- address.		
	See the second address in the list. For example, c6402.ambari.apache.org		
irst NameNode HTTP (WebHDFS) Click HDFS > Configs > Advanced > Advanced hdfs-site > dfs.namenode.http- address			
	See the first address in the list. For example, c6401.ambari.apache.org		
Second NameNode HTTP (WebHDFS) Address	Click HDFS > Configs > Advanced > Advanced hdfs-site > dfs.namenode.http- address		
	See the second address in the list. For example, c6402.ambari.apache.org		
First NameNode HTTPS (WebHDFS) Address	Click HDFS > Configs > Advanced > Advanced hdfs-site > dfs.namenode.https- address		
	See the first address in the list. For example, c6401.ambari.apache.org		
Second NameNode HTTPS (WebHDFS) Address	Click HDFS > Configs > Advanced > Advanced hdfs-site > dfs.namenode.https- address		
	See the second address in the list. For example, c6402.ambari.apache.org		
Failover Proxy Provider	Click HDFS > Configs > Advanced > Advanced hdfs-site > dfs.client.failover.proxy.provider[nameservice]		
Umask	Click HDFS > Configs > Advanced > Advanced hdfs-site > fs.permissions.umask- mode		
	The default value is 022. Do not change this value unless you are sure that you understand the effects of changing the value on your Hive View cluster. The umask property defines the file mode creation mask, which controls how file permissions are configured in new files.		
Auth To Local	Click HDFS > Configs > Advanced > Advanced core-site > hadoop.security.auth_to_local		

Property	Value
YARN Application Timeline Server URL*	Click YARN > Configs > Advanced > Application Timeline Server > yarn.timeline- service.webapp.address. When you enter the value in the view definition, pre-pend "http://" to the value you find in the YARN advanced configuration settings. For example, http://c6401.ambari.apache.org:8188
YARN ResourceManager URL*	Click YARN > Configs > Advanced > Advanced yarn-site > yarn.resourcemanager.webapp.address. When you enter the value in the view definition, pre-pend "http://" to the value you find in the YARN advanced configuration settings. For example, http:// c6401.ambari.apache.org:8088

Table 9.3. Cluster Configuration Values for the Hive View 1.5

Property	Value
Hive Session Parameters For secured clusters, see Kerberos Setup for Hive Views	Not required to be populated. If populated, use the following as an example, transportMode=http;httpPath=cliservice
WebHDFS Username	\$(username)
Scripts HDFS Directory*	/user/\${username}/hive/scripts
Jobs HDFS Directory*	/user/\${username}/hive/jobs
Default script settings file*	/user/\${username}/.\${instanceName}.defaultSettings
HiveServer2 JDBC URL*	jdbc:hive:// <host machine="" of="" running<br="" the="">hiveserver2>:10000</host>
WebHDFS FileSystem URI*	WebHDFS FileSystem URI* Click HDFS > Configs > Advanced > Advanced hdfs-site > dfs.nameserviceid.http- address. FOR HA: Click HDFS > Configs > Advanced > Advanced hdfs-site > dfs.nameservice.id. When you enter the value in the view definition, pre-pend "webhdfs://" to the value you find in the advanced HDFS configuration settings. For example, webhdfs:// c6401.ambari.apache.org:50070 or webhdfs:// nameserviceid
YARN Application Timeline Server URL*	Click YARN > Configs > Advanced > Application Timeline Server > yarn.timeline-service.webapp.address. When you enter the value in the view definition, pre- pend "http://" to the value you find in the YARN advanced configuration settings. For example, http:// c6401.ambari.apache.org:8188
YARN ResourceManager URL*	Click YARN > Configs > Advanced > Advanced yarn- site > yarn.resourcemanager.webapp.address. When you enter the value in the view definition, pre- pend "http://" to the value you find in the YARN advanced configuration settings. For example, http:// c6401.ambari.apache.org:8088

For NameNode High Availability

The following values must be entered for primary and secondary NameNodes:

Table 9.4. Hive View Settings for NameNode High Availability

Property	Value
First NameNode RPC Address or Second NameNode RPC Address	Select the primary or secondary NameNode to view settings from that host in the cluster. See how to get the NameNode RPC address [50]. When you enter the value in the view definition, pre-pend "http://" to the value you find in the advanced hdfs-site settings. For example, http://c6401.ambari.apache.org:8020

Property	Value
First NameNode HTTP (WebHDFS) Address or Second NameNode HTTP (WebHDFS) Address	Click HDFS > Configs > Advanced > Advanced hdfs-site > dfs.namenode.http-address. When you enter the value in the view definition, pre-pend "http://" to the value you find in the advanced hdfs-site settings. For example, http://c6401.ambari.apache.org:50070

To get First NameNode RPC Address values:

 Navigate to the HDFS service page in Ambari that contains links to individual NameNodes. Click NameNode (primary) or SNameNode (secondary) to view the host page:

Figure 9.3. HDFS Service Page in Ambari

े	HDFS	Summary	Heatmaps	Configs	Quick Links-	Service Actions -

3.2. User Permissions for Hive Views

After saving the Hive View instance definition, grant permission on the view for the set of users who can use the view:

Permissions					
Permission	Grant permission to these users	Grant permission to these groups			
Use	admin	Add Group			
Local Cluster P	ermissions				
Grant Use per	se permission for the following mycluster Roles:				
	 Cluster Administrator 				
	 Cluster Operator 				
	Service Operator				
	 Service Administrator 				
	Cluster User				
	Check All Clear All				

Figure 9.5. Granting User Permissions to Hive Views

3.3. Kerberos Setup for Hive Views

To set up basic Kerberos for views, see "Set Up Kerberos for Ambari Server" in Hortonworks Data Platform Apache Ambari Security. After you have set up basic Kerberos for the Hive View, Hive requires the following additional setting:

Property	Value	
WebHDFS Authentication	auth=KERBEROS;proxyuser= <ambari-principal></ambari-principal>	
		Note
		This property is only needed if the view is Custom Configured or Ambari Server is Kerberized

4. Using the Hive View

Use the Hive View to:

- Browse databases
- Write and execute queries
- Manage query execution jobs and history

Tip

To analyze Hive query execution on the Tez execution engine, use the Ambari Tez View, which provides a graphical view of executing Hive queries. For more information refer to:

Using the Tez View section of this guide How to Analyze or Debug Hive Queries posting on Hortonworks Community Connection

4.1. Query Tab

Click the **Query** tab to browse database tables and columns and to build, execute, and debug queries.

Database Explorer

The Database Explorer enables you to view all databases and tables in Hive that you have permissions to view. It is designed to navigate a large number of databases, tables, and columns:

Figure 9.6. Hive View Database Explorer

Database Explorer	c
consumption	•

Features of Database Explorer:

- Click the refresh icon in the top right to view tables that were created since the Hive View session began.
- Select a database from the drop-down list. All queries in the current tab are then run against the selected database. You can also edit the drop-down list to enable substring searches over a large number of databases.
- Use the Search tables and Search columns fields to search when you have a large number of tables and columns.
- Browse the Databases tab to view all of the databases, tables, and columns. This is useful when you are authoring queries. The icon to the right of a table enables you to see sample data within that table.

Query Editor

You can author and execute queries in the Query Editor:

Figure 9.7. Query Editor

Ambari MyClus	ster (Engel Ba		Dashboard	Services	Hosts	Alerts	Admin	III 🔺 🖬	ibari-qa •
Hive Query Saved	Queries His	tory UDFs

sub_metering_2 sub_metering_3 power3 power4 default	DOUBLE	Execute Explain Sevelat						New Works	

Features and Behavior of Query Editor

- All queries contained in a Worksheet tab execute sequentially, and they run in the same session. Running all queries in one pass requires handling the output of multiple select statements and is not supported in the 1.0 version.
- To run a specific query, highlight it, and click **Execute**.
- When the first query is executed in a Worksheet, a Tez session is opened.
- Click Save as to save your query.
- Double-click the **Worksheet** tab to rename the query, click **OK**, and then **Save as** to save the query with the new name.
- Click **New Worksheet** to open a new worksheet tab. Queries executed from the new worksheet tab will execute in a different session. Queries from different worksheets can execute in parallel.
- Press CTRL + space to autocomplete query statements.
- Click the double arrow icon in the upper right corner of the Query Editor to expand the Worksheet area and cover Database Explorer. Click the icon again to collapse the Worksheet and make Database Explorer available again.
- Click the icon at the bottom of the Worksheet window and drag it down to expand the authoring space.
- Query results and logs display below the query when it is executed.

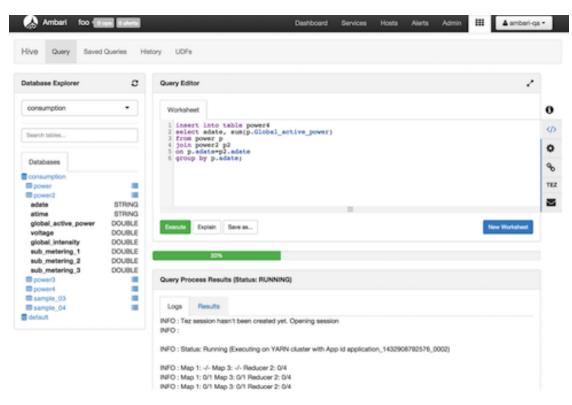

Figure 9.8. Query Results and Logs in Hive View Query Editor

Query Editor Settings

Click the gear icon on the right margin of the worksheet to access settings for the Query Editor. Then click **Add**, select a setting parameter from the drop-down list, and then select a value for the parameter. Query Editor settings are configured per worksheet.

To save settings as default settings so they are applied each time that a new worksheet is opened, click **Save Default Settings** in the upper right corner of the settings window.

Click **SQL** to the right of the Worksheet window to exit settings and return to the Query Editor authoring pane.

Text Explain and Visual Explain

There are two options that help you understand how your queries are executed. One is a textual explanation of your query and the other form explains the query visually as a diagram. In future releases, column lineage will be added.

The **Explain** button in the lower left corner of the Worksheet window launches a textual explanation:

	_

Figure 9.9. Query Editor Textual Explain Feature

To launch the Visual Explain diagram, click the link icon to the right of the Worksheet window. If the query is running, Visual Explain shows the query execution progress per vertex:

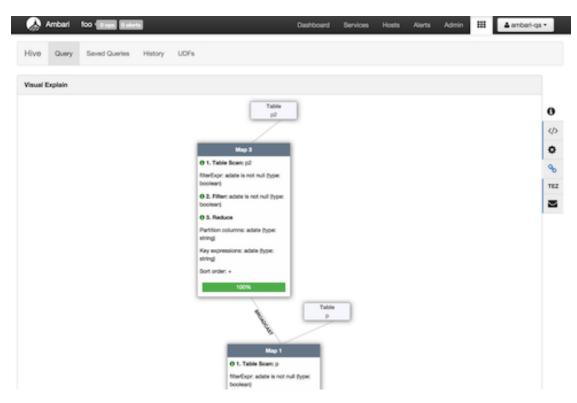

Figure 9.10. Query Editor Visual Explain Feature

Debugging Hive Query Execution Using the Tez View

Query execution can be debugged using the embedded Tez view. To access the Tez view, click **TEZ** in the toolbar on the right of the Worksheet window:

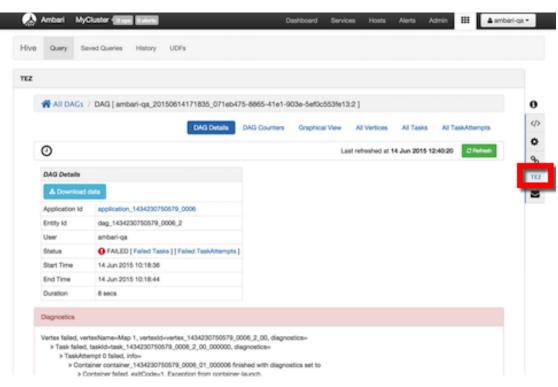

Figure 9.11. Tez View Query Debugging Option

When a query fails, the Status field displays **FAILED** and there is a link to Failed Tasks and the error displays on the first page. Click **Download data** to get the data for the task. For further details on debugging, see Using the Tez View.

Errors and Alerts

Errors and alerts can be viewed by clicking the envelope icon in the toolbar to the right of the Worksheet window. When the icon is clicked, all the messages are shown with a one-line summary per message:

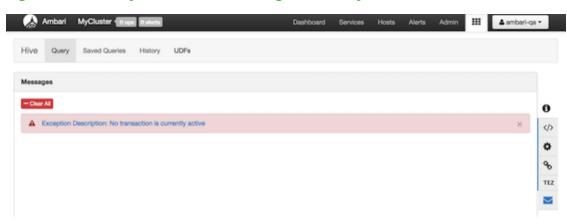

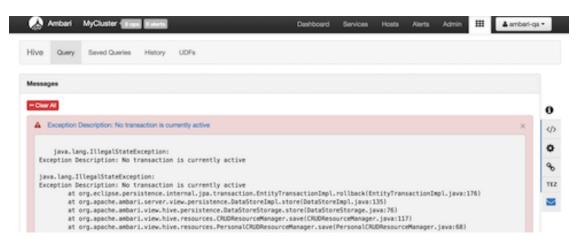

Figure 9.12. Query Editor Error Message Summary Window

If you want to view details of the errors, expand the summary by clicking it. The details text can be copied into a bug report:

Figure 9.13. Query Editor Error Message Details Window

4.2. Saved Queries Tab

The Saved Queries tab shows all the queries that have been saved by the current user. Click the gear icon to the right of the query list to view the history of a query or to delete it:

Figure 9.14. Saved Queries Tab

🛛 🚕 Ambari cn105PertC 📲	2 ops 1 alert		Deshboard	Services	Hosts 🚺	Alerts	Admin	iii 🔺 admin 🕶
Hive Query Saved Queries	History UDFs							
preview	ttie	•	database	•	owner		•	Clear filters
select dt.d_year ,item.i_brand_id	Query3		tpcds_bin_orc_200		admin			0

4.3. History Tab

You can view the history of all jobs run by the current user in the History tab. It pulls history from the Application Timeline Server database. All queries for which logs are present in that database are displayed here. This means that regardless of the source of the query, (CLI, JDBC/ODBC, Hive View) it will appear here on the History tab. Queries that have not been assigned a name, such as those created in the Hive View, appear as query text. For example, see the insert statement that was submitted by CLI in the following image:

Figure 9.15. History Tab

🝌 Ambari	foo f 0 ops 0 alerts			Dashboard Services	Hosts Alerts	Admin III 🔺 ambari-ga •
Hive Query	y Saved Queries H	istory UDFs				
title	٠	status	\$ 05/29/2015	05/29/2015		37sec
Worksheet		RUNNING	12 minutes ago		0	2
insert into to select adate, from power p join power2 p2 on p.adate=p2. group by p.ada	sum(p.Global_active_po adate	wer)				Stop execution
nsert into table p	ower3 select adate, sum	SUCCEEDED	19 minutes ago		31	

For queries that are submitted from the Hive View, a Stop Execution button is available to enable you to end a currently running query. When you select a query by clicking the title in the first column, that query appears on a new sub-tab in the Query tab where it can be analyzed and debugged.

4.4. UDF Tab

User-defined functions (UDFs) can be added to queries by pointing to a JAR file on HDFS, which contains the UDF definition. After the UDF is added here, an Insert UDF button appears in the Query Editor that enables you to add the UDF to your query:

Figure 9.16. UDF Tab

Ambari cn105PerfC 💷 🚥	er.	Dashboard Services	Hosts 🚺 Alerts /	kdmin 🏭 🔺 admin 🕶
Hive Query Saved Queries History	UDFs			
file resource	udf name	udf class name		Cear filters New UDF
Select File Resource	udfiname	udf class name		Cancel Save

4.5. Upload Table tab

In the Upload Table tab, you can upload files which contain the rows of the Apache Hive table. The Upload Table command supports various input file formats. On uploading, it creates a new Hive table with the data.

Input File Formats:

CSV, XML, and JSON files are supported for input.

CSV

Supported types are:

• CSV with custom field delimiter (default is comma,)

• Quote character (default is double quote ") Escape character (default is backslash \)

The row delimiter must be \n or \r or \r\n. If Is first row header? is selected then first row of the file is treated as column names. During preview this can be changed by clearing this field but other delimiters should not be changed during the preview. The number of columns in the table and their order is defined by the first line of the file, irrespective of whether it represents column names nor not. If there are extra columns in line 2 onwards, they are ignored. If there are lesser columns in line 2 onwards then the rest of the columns are assumed null values.

XML

The format of the contents in the XML file should be as shown below:

</rov <row

	<row></row>
	<col name="col1Name"/> row1-col1-Data
	<col name="col2Name"/> row1-col2-Data
	<col name="col3Name"/> row1-col3-Data
	<col name="col4Name"/> row1-col4-Data
w>	
v>	
	<col name="col1Name"/> row2-col1-Data
	<col name="col2Name"/> row2-col2-Data
	<col name="col3Name"/> row2-col3-Data

```
<col name="col4Name">row2-col4-Data</col>
```

</row>

The root tag must be . Inside there can be any number of <row> tags representing one row of the table. Inside each <row> tag there can be any number of <col> tags representing columns of the row. Each <col> tag must have a "name" attribute, which will be treated as the name of column. Column values should be within the <col> tag. The names, number and order of columns are decided by the first <row> entry. The names of column and datatypes can be changed during the Preview.

JSON

The following json format is supported: [{ "col1Name" : "value-1-1", "col2Name" : "value-1-2"}, { "col1Name" : "value-2-1", "col2Name" : "value-2-2"}]

The file should contain a valid json array containing any number of json objects. Each json object should contain column names as property and column values as property values. The names, number and order of columns in the table are decided from the first object of the json file. The names and datatype of column can be edited during the preview step. If some json objects have extra properties then they are ignored. If they do not have some of the properties then null values are assumed. Note that extension of files cannot be ".json"

To import a file into the Hive view:

- 1. Select Upload from Local or Upload from HDFS.
- 2. Select the input file format File type by specifying CSV, XML, or JSON.
- 3. If the File Type is CSV, you can select the **Field Delimiter**, the **Escape Character**, the **Quote Character** and **Is first row header?** values for CSV by clicking on the gear icon.
- 4. If you selected **Upload from Local**, you can choose the file from your local machine. Otherwise, enter the full HDFS path and click **Preview**. The file is partially read from client's browser or HDFS and the preview is generated with a suggested table name, column names, column data types and 10 rows from the data file.
- 5. You can select **Database** from the drop-down list, change the suggested table name, column names, column types, precision and scale and hive storage type **Stored as** as required.
- 6. If Stored as is TEXTFILE, then a gear next to it is enabled and you can click it to select **Fields Terminated By**, and **Escape By** to be used in creation of the Hive table.
- 7. If Stored as is NOT TEXTFILE, another option Contains endlines? is enabled. If the column values in your file contain endline characters, ("\n" newline, ASCII 10 or "\r" carriage return, ASCII 13) then you must check this field for proper handling otherwise unexpected results might occur. Endline characters are not supported in TEXTFILE format.
- 8. Click **Upload table**. The actual table and temporary table (Stored as TEXTFILE) is created. After this the data rows from the file are inserted into the temporary table followed by Insert from temporary table to actual table.
- 9. On success the temporary table is deleted and workflow completes.

In case of failure, an error is reported and the temporary table and actual tables are deleted. You can see the error message by clicking the message icon at the top right. Clicking again on the message icon brings back the Upload Table page. You can perform any changes required and click **Upload** again to upload the same file or restart the process by selecting a different file.

5. Troubleshooting

Table 9.5. Troubleshooting Hive Views Errors

Error	Solution
User: root is not allowed to impersonate admin	HDFS has not been configured for Ambari as a proxy user. Refer to Setup HDFS Proxy User.
E090 HDFS020 Could not write file /user/admin/hive/jobs/ hive-job-1-2015-10-30_02-12/query.hql [HdfsApiException]	The user does not have a user directory in HDFS for the view to store metadata about the view. Refer to Setup HDFS User Directory.

10. Using the Pig View

Apache Pig is a scripting platform for processing and analyzing large data sets. Pig was designed to perform extract-transform-load (ETL) operations, raw data research, and iterative data processing. The **Pig View** provides a web-based interface to compose, edit, and submit Pig scripts, download results, and view logs and the history of job submissions.

This chapter explains:

- Configuring Your Cluster [62]
- Creating the Pig View Instance [64]
- Using the Pig View [69]

1. Configuring Your Cluster

For the Pig View to access HDFS, the Ambari Server daemon hosting the view needs to act as the proxy user for HDFS. This allows Ambari to submit requests to HDFS on behalf of the users using the Pig View. This is critical since the Pig View will store metadata about the user Pig scripts. This also means users that will access the Pig View must have a user directory setup in HDFS. In addition, the Pig View uses WebHCat to submit Pig scripts so the View needs a proxy user for WebHCat.

Note

If you are running views in an operational Ambari server (one that is operating the cluster) Ambari does this setup by default. You should verify that the setup described in the following subsections has been completed. If you are running views on a standalone server, you must setup proxy user settings manually, using the following instructions.

- Setup HDFS Proxy User [62]
- Setup WebHCat Proxy User [63]
- Setup HDFS User Directory [64]

1.1. Setup HDFS Proxy User

To set up an HDFS proxy user for the Ambari Server daemon account, you need to configure the proxy user in the HDFS configuration. This configuration is determined by the account name the **ambari-server** daemon is running as. For example, if your ambari-server is running as **root**, you set up an HDFS proxy user for **root** with the following:

- 1. In Ambari Web, browse to Services > HDFS > Configs.
- 2. Under the Advanced tab, navigate to the Custom core-site section.
- 3. Click Add Property... to add the following custom properties:

```
hadoop.proxyuser.root.groups="users"
hadoop.proxyuser.root.hosts=ambari-server.hostname
```

Notice the **ambari-server** daemon account name root is part of the property name. Be sure to modify this property name for the account name you are running the ambari-server as. For example, if you were running **ambari-server** daemon under an account name of **ambariusr**, you would use the following properties instead:

```
hadoop.proxyuser.ambariusr.groups="users"
hadoop.proxyuser.ambariusr.hosts=ambari-server.hostname
```

Similarly, if you have configured Ambari Server for Kerberos, be sure to modify this property name for the **primary Kerberos principal** user. For example, if ambari-server is setup for Kerberos using principal **ambari-server@EXAMPLE.COM**, you would use the following properties instead:

```
hadoop.proxyuser.ambari-server.groups="users"
hadoop.proxyuser.ambari-server.hosts=ambari-server.hostname
```

4. Save the configuration change and restart the required components as indicated by Ambari.

1.2. Setup WebHCat Proxy User

You must set up an HDFS proxy user for WebHCat and a WebHCat proxy user for the Ambari Server daemon account.

To setup the HDFS proxy user for WebHCat :

- 1. In Ambari Web, browse to Services > HDFS > Configs.
- 2. Under the Advanced tab, navigate to the Custom core-site section.
- 3. Click Add Property... to add the following custom properties:

```
hadoop.proxyuser.hcat.groups=*
hadoop.proxyuser.hcat.hosts=*
```

4. Save the configuration change and restart the required components as indicated by Ambari.

To setup a WebHCat proxy user for the Ambari Server daemon account, you need to configure the proxy user in the WebHCat configuration. This configuration is determined by the account name the **ambari -server** daemon is running as. For example, if your ambari - server is running as **root**, you set up an WebHCat proxy user for **root** with the following:

- 1. In Ambari Web, browse to Services > Hive > Configs.
- 2. Under the Advanced tab, navigate to the Custom webhcat-site section.
- 3. Click Add Property... to add the following custom properties:

```
webhcat.proxyuser.root.groups=*
webhcat.proxyuser.root.hosts=*
```

Notice the **ambari-server** daemon account name root is part of the property name. Be sure to modify this property name for the account name you are running the ambari-

server as. For example, if you were running **ambari-server** daemon under an account name of **ambariusr**, you would use the following properties instead:

```
webhcat.proxyuser.ambariusr.groups=*
webhcat.proxyuser.ambariusr.hosts=*
```

Similarly, if you have configured Ambari Server for Kerberos, be sure to modify this property name for the **primary Kerberos principal** user. For example, if ambari-server is setup for Kerberos using principal **ambari-server@EXAMPLE.COM**, you would use the following properties instead:

```
webhcat.proxyuser.ambari-server.groups=*
webhcat.proxyuser.ambari-server.hosts=*
```

4. Save the configuration change and restart the required components as indicated by Ambari.

1.3. Setup HDFS User Directory

The Hive View stores user metadata in HDFS. By default, the location in HDFS for this metadata is /user/\${username} where \${username} is the username of the currently logged in user that is accessing the Hive View.

Important

Since many users leverage the default Ambari admin user for getting started with Ambari, the /user/admin folder needs to be created in HDFS. Therefore, be sure to create the admin user directory in HDFS using these instructions prior to using the view.

To create user directories in HDFS, do the following for each user you plan to have use the Hive View.

- 1. Connect to a host in the cluster that includes the HDFS client.
- 2. Switch to the hdfs system account user.

su - hdfs

3. Using the HDFS client, make an HDFS directory for the user. For example, if your username is admin, you would create the following directory.

```
hadoop fs -mkdir /user/admin
```

4. Set the ownership on the newly created directory. For example, if your username is admin, you would make that user the directory owner.

```
hadoop fs -chown admin:hadoop /user/admin
```

2. Creating the Pig View Instance

- 1. Browse to the Ambari Administration interface.
- 2. Click Views, expand the Pig View, and click Create Instance.

- 3. On the Create Instance page, select **Version**. If multiple Pig View jars are present, choose one.
- 4. Enter the Details and Settings. The Instance Name appears in the URI, the Display Name appears in the Views drop-down list, and the Description helps multiple users identify the view:

Figure 10.1. Pig View Details and Settings

View	PIG	
Version	1.0.0	\$
Details		
Inc	stance Name	ETLPig D
	Sisplay Name	ETL Pig
	Description	Pig View for ETL team
		Ø Visible
Settings		
WebHD	FS Username	\${usemame}
WebHDFS A	Authentication	auth=SIMPLE
WebHC	Cat Username	
Scripts HDF	S Directory*	/user/\$(usemame)/pig/scripts
Jobs HDP	FS Directory*	/user/\$(usemame)/pig/jobs
Meta Hi	DFS Directory	/user/5[username]/pig/store

5. Scroll down, and enter the Cluster Configuration information, which tells the Pig View how to access resources in the cluster. For a cluster that is deployed and managed by Ambari, select Local Ambari Managed Cluster:

Figure 10.2. Pig View Cluster Configuration

luster Configuration		
Local Ambari Managed Clu	ister	
Cluster Name	MyCluster	\$
Custom		
ebHDFS FileSystem URI*	webhdfs://namenode:500	70
Logical name of the NameNode cluster		
List of NameNodes		
First NameNode RPC Address		
Second NameNode RPC Address		
First NameNode HTTP (WebHDFS) Address		
Second NameNode HTTP (WebHDFS) Address		
Failover Proxy Provider		
WebHCat Hostname*	webhcat-host.example.co	m
WebHCat Port*	50111	

6. Click **Save**, give Permissions to the appropriate users and groups, and click **Go to instance** at the top of the page to go to the view instance.

2.1. Getting Correct Configuration Values for Manually-Deployed Clusters

If you have manually deployed your cluster, you must enter cluster configuration values in the Pig View Create Instance page. The following table explains where you can find cluster configuration settings in Ambari.

Table 10.1. Finding Cluster Configuration Values for the Pig View in Ambari

Property	Value
Scripts HDFS Directory*	/user/\${username}/pig/scripts
Jobs HDFS Directory*	/user/\${username}/pig/jobs
WebHDFS FileSystem URI*	Click HDFS > Configs > Advanced hdfs-site > dfs.namenode.http-address. When you enter the value in the view definition, pre-pend "webhdfs://" to the value you find in the advanced HDFS configuration settings. For example, webhdfs:// c6401.ambari.apache.org:50070
WebHCat Hostname*	Click Hive > Configs > Advanced > WebHCat Server > WebHCat Server host to view the hostname. For example, c6402.ambari.apache.org
WebHCat Port*	Click Hive > Configs > Advanced > Advanced webhcat-site > templeton.port to view the port number. For example, 50111

For NameNode High Availability

The following values must be entered for primary and secondary NameNodes:

Table 10.2. Pig View Settings for NameNode High Availability

Property	Value
First NameNode RPC Address or Second NameNode RPC Address	Select the primary or secondary NameNode to view settings from that host in the cluster. See how to get the NameNode RPC address [66]. When you enter the value in the view definition, pre-pend "http://" to the value you find in the advanced hdfs-site settings. For example, http://c6401.ambari.apache.org:8020
First NameNode HTTP (WebHDFS) Address or Second NameNode HTTP (WebHDFS) Address	Click HDFS > Configs > Advanced > Advanced hdfs-site > dfs.namenode.http-address. When you enter the value in the view definition, pre-pend "http://" to the value you find in the advanced hdfs-site settings. For example, http://c6401.ambari.apache.org:50070

To get First NameNode RPC Address values:

 Navigate to the HDFS service page in Ambari that contains links to individual NameNodes. Click NameNode (primary) or SNameNode (secondary) to view the host page:

Figure	10.3. I	HDFS	Service	Page	in	Ambari
--------	---------	------	---------	------	----	--------

9	HDFS	Summary	Heatmaps	Configs	Quick Links+		Service Actions
•	YARN						
9	MapReduce2	Summary					No ale
2	Tez		NameNode	Started No alerts		Disk Remaining	1.1 TB / 1.3 TB (91.10%)
	Hive		SNameNode	Started No alerts		Blocks (total)	738
	HBase	Da		3 live / 0 dead / 0 decommiss	ioning	Block Errors	0 corrupt replica / 0 missing / 0 under replicated
1	Pig		JournalNodes	0/0 JournalNodes Live		Total Files + Directories	947

Display	Name	My Pig View	
Descri	iption	description	
		Visible	
Permissions			
Permission	Grant	permission to these users	Grant permission to these groups
Use			
Settings			✓ Edit

Figure 10.5. Granting User Permissions to Pig Views

2.3. Kerberos Setup for Pig Views

To set up basic Kerberos for views, see "Set Up Kerberos for Ambari Server" in the Ambari Security Guide. After you have set up basic Kerberos for the Pig View, Pig requires that WebHDFS Authentication be set to auth=KERBEROS;proxyuser=<ambari-userprincipal>.

Note

This property is only needed if the view is Custom Configured or Ambari Server is Kerberized before 2.4.0.

For example, see the following figure:

Figure 10.6. Kerberos Settings for Pig Views

Properties		🖌 Edit
WebHDFS FileSystem URI*	webhdfs://erik-views-1.c.pramod-thangaii.internal:50070	
WebHDFS Username	\$(usemame)	
WebHDFS Authentication	auth=KERBEROS;proxyuser=ambarluser	
WebHCat URL*	http://erik-views-3.c.pramod-thangali.internal:50111/templeton/v1	
WebHCat Username	\${usemame}	
Dataworker Username	\$(usemame)	
Scripts HDFS Directory*	/user/\$(usemame)/pig/scripts	
Jobs HDFS Directory*	/user/\$(usemame)/pig/jobs	
Meta HDFS Directory	/user/\$(usemame)/pig/store	

3. Using the Pig View

Use the Pig View to:

- Write Pig scripts
- Execute Pig scripts
- Add user-defined functions (UDFs) to Pig scripts
- View the history of all Pig scripts run by the current user

3.1. Writing Pig Scripts

Navigate to the Pig View instance Scripts page, and click **New Script** in the upper right corner of the window. Name the script in the New Script dialog box, click **Create**, and enter your script into the editor. After you have written the script, you can use the execute button on the upper right to run it. Check the box that is adjacent to the execute button to use Tez instead of the default MapReduce engine.

The following figure shows a running Pig script:

		vices Hosts Alerts	Admin III	▲ ambari-qa •
B PREETL 1	Soript History			
1 Dieve	Pig_ETL_1 🧪		C Execute on Tez	Decute +
Copy Copy Delete	PRG heper - UCF heper - 1 batting = load 'Batting.cev' using FigStorage(', 2 runs = FOREACH batting GENERATE \$0 as playerID, 3 grp_data = GROUP runs by (year); 4 max_runs = FOREACH grp_data GENERATE group as gr 5 join_max_run = JOIN max_runs by (\$0, max_runs), 6 join_data = FOREACH join_max_run GENERATE \$0 as 7 dump join_data;	\$1 as year, \$8 as r rp,MAX(runs.runs) as runs by (year,runs)	rune; max_rune;);	1 <u>6-15-02-55-pig</u>
	Arguments	-	Pig argument	+ Add

Figure 10.7. Pig Script Running in the Pig View

3.2. Viewing Pig Script Execution History

The History tab shows the history of Pig scripts run by the current user. A particular script in history can be clicked to open it in a new Script tab to view its details:

Figure 10.8. Pig View Script History Tab

🔬 Ambari MyCluster (Depa D	alerts		Dashboard	Services	Hosts	Alerts	Admin	ш	≜ amb	bari-qa •
() Scripts	History									
🗩 UDFs	Date	Script	Status		Duration		Actions			
History	2015-06-15 08:00	PIQ_ETL_1	RUNNING				2 Delete			
						Sł	10w: 10	• 1	1 of 1	~ >

3.3. User-Defined Functions (UDFs) Tab

UDFs can be added to Pig scripts by clicking **Create UDF** in the upper right corner of the UDFs window. In the Create UDF dialog box, point to a UDF in the system by specifying the name and path:

Figure 10.9. Pig View UDFs Tab

🖋 uo	Fs	Name	Path		Owner	,			
() His	tory	No UDFs to display							

11. Using the Slider View

Slider is a framework for deploying and managing long-running applications on YARN. When applications are packaged using Slider for YARN, the **Slider View** can be used to help deploy and manage those applications from Ambari.

Important

This view has been marked deprecated.

1. Deploying the Slider View

Refer to the Ambari Administration guide for general information about Managing Views.

- 1. From the Ambari Administration interface, browse to the Views section.
- 2. Click to expand the Slider view and click Create Instance.
- 3. Enter the instance name, the display name and description.
- 4. Enter the configuration properties for your cluster.

Property	Description	Example
Ambari Server URL (required)	The Ambari REST URL to the cluster resource.	http://ambari.server:8080/api/v1/ clusters/MyCluster
Ambari Server Username (required)	The username to connect to Ambari. Must be an Ambari Admin user.	admin
Ambari Server Password (required)	The password for the Ambari user.	password
Slider User	The user to deploy slider applications as. By default, the applications will be deployed as the "yarn" service account user. To use the current logged-in Ambari user, enter \${username}.	joe.user or \${username}
Kerberos Principal	The Kerberos principal for Ambari views. This principal identifies the process in which the view runs. Only required if your cluster is configured for Kerberos. Be sure to configure the view principal as a proxy user in core-site.	view-principal@EXAMPLE.CO
Kerberos Keytab	The Kerberos keytab for Ambari views. Only required if your cluster is configured for Kerberos.	/path/to/keytab/view- principal.headless.keytab

5. Save the view.

12. Using the SmartSense View

The SmartSense View allows Hortonworks support subscription customers to capture diagnostic data for two purposes:

- To receive recommendations on performance, security, and operational changes based on your server hardware, HDP services deployed, and your use cases.
- To quickly capture diagnostic information about services and hosts when working with support to troubleshoot a support case.

This chapter explains:

- Configuring Your Cluster [73]
- Creating the SmartSense View Instance [73]
- Using the SmartSense View [75]

1. Configuring Your Cluster

When you deploy a cluster with Ambari, a SmartSense View instance is automatically created as long as an Ambari Agent is deployed on the host running the Ambari Server.

Important

If an Ambari Agent is not installed on the Ambari Server host, the view will not be automatically created, and you will have to add it manually using the instructions in Creating the SmartSense View Instance.

Before accessing the SmartSense View, you should enter your SmartSense user ID, account name (both are available in the Hortonworks support portal in the **Tools** tab), and email address in the SmartSense service configuration properties.

2. Creating the SmartSense View Instance

- 1. Browse to the Ambari Administration interface.
- 2. Click Views, expand the HORTONWORKS_SMARTSENSE menu, and click Create Instance:

Amberi				▲ admir
Clusters	Views		Search	0
mycluster C Permissions	View Name	Instances		
Go to Dashboard	> CAPACITY-SCHEDULE	IR 1.0.0 (1)		
Versions	> FILES	1.0.0 (1)

	Settings	
	hst.server.url*	http://i06401.ambari.apache.org/9000/
	hst.server.username*	admin
	hst.server.password*	

4. Enter the following view instance details:

Table 12.1. SmartSense View Instance Details

Property	Description
Instance Name	This is the SmartSense view instance name. This value should be unique for all SmartSense view instances you create. This value cannot contain spaces and is required.

Property	Description
Display Name	This is the name of the view link displayed to the user in Ambari Web.
Description	This is the description of the view displayed to the user in Ambari Web.

5. Enter the following view instance settings:

Table 12.2. SmartSense View Instance Settings

Property	Description
hst.server.url	This is the HST server URL. This should be http:// <pre><hr/><hr/><hr/><hr/><hr/><hr/><hr/><hr <="" td=""/></pre>
hst.server.username	The default username is 'admin'.
hst.server.password	Unless changed after installation, the default password is 'admin'.

6. Click Save.

3. Using the SmartSense View

Use the SmartSense View to:

- Capture a bundle
- Set a bundle capture schedule
- View and download captured bundles

13. Using the Storm View

Storm provides a real-time, scalable, and distributed solution for data streamed from realtime sources such as machine sensors, supporting data ingestion, processing, and real-time response. Typical use cases include automated systems that respond to sensor data by notifying support staff, or an application that places a proximity-based advertisement on a consumer's smart phone.

This chapter explains:

- Configuring Your Cluster [76]
- Creating the Storm View Instance [76]
- Using the Storm View [78]

Important

Before creating the Storm view instance, prepare your Ambari Server for hosting views. It is strongly recommended you increase the amount of memory available to your Ambari Server, and that you run additional "standalone" Ambari Servers to host the views. See Preparing Ambari Server for Views and Running Ambari Server Standalone for more information.

1. Configuring Your Cluster

The Storm View requires that the cluster is managed by Ambari; the view utilizes the Ambari Server API.

2. Creating the Storm View Instance

1. Browse to the Ambari Administration interface: from the dashboard, open the administrator account menu and click **Manage Ambari**:

						About
HDFS	Metrics Heat	tmaps Config History				Manage Ambe
A YARN	Metric Actions *	Last 1 hour •				Settings
MapReduce2					_	Sign out
III Tez	HDFS Disk Usage	DataNodes Live	HDFS Links	Memory Usage	Network U	Isage
A Hive			NameNode	2	39.0 KB	4
😐 Pig	63%	3/3	Secondary NameNode		39.0 KB	

2. Click Views, expand the Storm_Monitoring menu, and click Create Instance:

Clusters	Views C		Search
storm (3 View Name	Instances	
Go to Dashboard	> CAPACITY-SCHEDULE	R 1.0.0 (0)	
Versions	> FILES	1.0.0 (0)	
Remote Clusters	> HIVE	1.0.0 (0) , 2.0.0 (0)	
	> PIG	1.0.0 (0)

Management Users Groups	Settings Storm Hostname*	storm-host-node1.com
	Storm Port*	8744
		Cancel Save

4. Enter the following view instance details:

Property	Description	Example Value
Instance Name	This is the Storm view instance name. This value should be unique for all Storm view instances you create. This value cannot contain spaces, and it is a required setting.	
Display Name	This is the name of the view link displayed to the user in Ambari Web.	StormView
Description	This is the description of the view displayed to the user in Ambari Web.	StormView

Table 13.1. Storm View Instance Details

5. Enter the following view instance settings:

Table 13.2. Storm View Instance Settings

Property	Description	Example Value
Storm Hostname	This is the hostname where the Storm UI Server is running.	storm-host-nodel.com
Storm Port	This is the port where the Storm UI Server is listening.	8744

Settings depend on cluster and deployment factors in your environment. You can typically leave the default settings unless you are using the Storm View with a Kerberosenabled cluster. For more information, refer to the Ambari Security Guide and Configuring Views for Kerberos.

6. Click Save.

3. Using the Storm View

Use the Storm View for the following types of operations:

- Monitor Storm cluster status and review configuration settings.
- Monitor Storm topologies, review configuration settings, perform topology actions such as Activate, Deactivate, and Kill, and perform topology rebalancing to increase worker JVMs and component parallelism.
- Access component metrics, debug logs, and jstack outputs; debug and profile worker JVMs.

3.1. Monitoring Storm Cluster Status: the Cluster Summary Page

The landing page for the Storm view shows current cluster status and nimbus configuration.

It shows the available nimbus host(s), and for a nimbus HA, denotes which host is a leader. It also shows all available supervisor hosts and currently deployed topologies. Here is an example landing page:

EXECUTOR	TASKS		Topology Listing				
	2 8	28	Topology Name	50	eus.	Uptin	ve .
SUPERVISOR		1015	wordcount		THE	52m 2	
(100%) (759		Supervisor Summary				(
	7	5%	Host	Slots	CPU	Memory	Uptime
			o6601.ambari.apache.org	(100 M)	(0%)	54 N	5h 50m 7s
Nimbus Summary		6	c6602.ambari.apache.org				Sh 9m Sds
lost:Port	Status	Uptime		50%	(ox)	(27%)	
6602.ambari.apache.org.6627	Leader	1h 10m 38s					

The lower left section of the summary page shows resource utilization of supervisors:

Supervisor Summary				C
Host	Slots	CPU	Memory	Uptime
c6601.ambari.apache.org	100 %	0%	54%	1h 10m 7s
c6602.ambari.apache.org	50%	0%	27 %	1h 9m 18s

The upper right section shows the current status of the deployed topology:

Topology Listing		(3
Topology Name	Status	Uptime	
wordcount	ACTIVE	31s	

Click on the "Nimbus Configuration" section to list Storm configuration settings:

limbus Configuration	
Search By Key	Q.
Key	Value
client.jartransformer.class	org.apache.storm.hack.StormShadeTransformer
drpc.invocations.port	3773
logviewer.max.per.worker.logs.size.mb	2048
nimbus.blobstore.class	org.apache.storm.blobstore.Localif'sBlobStore
nimbus.childopts	-Xmx1024m-javaagent.lusr/hdp/current/storm-nimbus/contrib/storm-jmuetric/lib/jmuetric- 1.0.4.jar=host=localhost.port=8649;wireformat31x=true_mode=multicast.config=/usr/hdp/current/storm-nimbus/contrib/storm- jmuetric/confi/jmuetric-confuml.process=Nimbus_JVM
resource.aware.scheduler.eviction.strategy	org.apache.storm.scheduler.resource.strategies.eviction.DefaultEvictionStrategy
scheduler.display.resource	false
storm.cluster.mode	distributed
storm.group.mapping.service	org.apache.storm.security.auth.ShellBasedGroupsMapping
storm.messaging.netty.client_worker_threads	1
storm.messaging.netty.server_worker_threads	1
storm.thrift.transport	org.apache.storm.security.auth.SimpleTransportPlugin
upervisor.localizer.cache.target.size.mb	10240
upervisor.run.worker.as.user	false
opology built in metrics bucket size secs	60
topology.max.error.report.per.interval	5

3.2. Monitoring Topology Status: the Topology Summary Page

The topology summary page contains metrics and directed acyclic graphs (DAG) that show deployed topology components and topology debugging features.

You can select which window for which to review metrics. By default the view will show metrics for "All Time."

POLOGY SUMMARY	TOPOLOGY ST	TATS				
ID: wordcount-2-1466189929	Window	Emitted	Transferred	Complete Latency (ms)	Acked	Falled
Owner: storm Status: ACTIVE	10m Os	65240	35000	0		
Uptime: 3m 29s	3h Om Os	65240		0		
Workers: 3			35000	-		
Decutors: 28	5d Oh Om Os	65240	35000	0		
Taska: 28	All time	65240	35000	0		
Memory: 2496						
rdcount						
**		+				

On the right side above panel, there are several topology actions buttons. These buttons allow you to perform several actions: Activate (highlights when topology status is deactivated), Deactivate, Rebalance, Kill, and Changing log level.

Window	NI time		System Summary	OFF	Debug	OFF	▶ ■ ⊕ ● D
--------	---------	--	----------------	-----	-------	-----	-----------

Rebalancing a Topology

To adjust the number of workers for the topology and the parallelism of each component in the topology, use the rebalance button.

/ wordcool	Rebalance Topolo	gy		×	
2	Workers*:	0	• 4		
Y	spout*:	5		1	
e-2-14661899	count*:	12		8	r (ms)
	split*:	8		1	
	Wait Time*:	30		1	
				Close Save	

Changing the Logging Level of a Running Topology

This feature facilitates topology debugging, by allowing you to temporarily enable debug log level and see any issues in a topology.

To use this feature, edit the Logger to update the class name for which you would like to add a log level.

Modify the logger levels for topology. Note that applying a setting resta	Change Log Level rts the timer in the workers. T	o configure the root logger, us	the name ROOT.	
Logger	Level	Timeout	Expires At	Action
comyour organization LoggerName	ALL	- 30		

For example, if you would like to see debug logs in the count bolt of the sample word count topology supplied with Storm, add the classname as org.apache.storm.starter.WordCount.

Sampling Events in a Running Topology

This feature allows users to debug and see the events that are flowing through the topology, essentially sampling events from a running topology and storing them in a log file.

To use this feature, turn the Debug switch to "On":

Window	Alttime	•	System Summary	OFF	Debug	OFF		Þ = 4	0 0
		- 0					· ·		

	Do you really sampling perc	want to debug th centage.	his topology	? If yes, please	e, specify ×			• D
TOPOLOGY SUMMARY	10							
ID: wordcount-2-14661899 Owner: storm					No Yes	(ms)	Acked	Failed
Status: ACTIVE		1011 05	411207	20072				
Uptime: 25m-4s		3h Om Os	889920	477240	0			
Workers: 3		1d Oh Om Os	889920	477240	0			
Encutors: 28		10 OH OR OS	001120	477240				

The event logger will sample the given percentage of incoming tuples and write them to the log for users to see the incoming tuples at each stage of topology. We recommend that you not set this to a higher percentage, because it can fill up the logs on disk very quickly.

3.3. Looking Up Configuration Values: the Component Summary Page

On the Component Summary page, you can drill down to a individual component in a topology to see relevant stats for the component and access debug logs and jstack outputs.

	ari storm (Digits 2 alertis				Dashboard S	ervices Hosts	Alerts Admir		A admin
\			<u> </u>							
7 19	pology Listing	wordcount	spout							
Window	All time		System	Summary	OFF	De	bug 0	FF		•
OMPON	NENT SUMM	ARY		SPOUT STATS						
	ID: spout			Window	Emitted	Transferred	Complete Late	ency (ms)	Acked	Failed
Topo	Angy: wordcou	r6		3h Om Os	94360	94360	0,000		0	0
	dors: 5			1d Oh Om Os	94360	94360	0,000		0	0
	laska: S			All time	94360	94360	0,000		0	0

c6602.ambari.apache.org:6700	[26-26]	I.
c6601.ambari.apache.org:6701	[27-27], [24-24]	

14. Using the Tez View

Tez is an framework for building high performance batch and interactive data processing applications. Apache Hive and Pig use the Tez framework. When you run a job such as a Hive query or Pig script using Tez, you can use the Tez View to track and debug the execution of that job. Topics in this chapter describe how to configure, deploy and use the Tez View to execute jobs in your cluster:

- Configuring Your Cluster for Tez View [85]
- Creating or Editing the Tez View Instance [86]
- Using the Tez View [90]

Tip

See How to Analyze or Debug Hive Queries on Hortonworks Community Connection for a short how-to article and links to demonstration videos about how you can use Tez View to monitor and troubleshoot Hive queries running on Tez.

1. Configuring Your Cluster for Tez View

When you deploy a cluster with Ambari, a Tez View instance is automatically created. However, you must verify that the configurations listed in the following table have been correctly set.

If you have manually deployed your cluster, you must set the properties listed in the following table to configure your cluster before you create the Tez View on your standalone Ambari server.

To configure your cluster for the Tez View:

1. Confirm the following configurations are set:

Table 14.1. Cluster Configurations for Tez View

Component	Configuration	Property	Comments
YARN	yarn-site.xml	yarn.resourcemanager. system-metrics- publisher.enabled	Enable the generic history service in the Timeline Server. Verify that this property is set to true.
YARN	yarn-site.xml	yarn.timeline- service.enabled	Enable the Timeline Server for logging details. Verify that this property is set to true.
YARN	yarn-site.xml	yarn.timeline- service.webapp.address	Value must be the IP:PORT on which the Timeline Server is running.

2. If you changed any settings, you must restart the YARN ResourceManager and the Timeline Server for your changes to take effect.

Important

If you do not need to reconfigure the Ambari-created Tez View, see Using the Tez View.

2. Creating or Editing the Tez View Instance

Depending on whether you must create a new Tez View instance for a manually deployed cluster or modify an Ambari-created Tez View, see one of the following sections:

- ???TITLE??? [86]
- ???TITLE??? [87]

To modify a Tez View instance on an Ambari-managed cluster:

- 1. Navigate to the Ambari Administration interface.
- 2. Click Views and expand the Tez View.
- 3. On the Create Instance page, change the appropriate configuration parameters.
- 4. Select Local Ambari-Managed Cluster:

Figure 14.1. Tez View Create Instance Page

0.7.0.2.3	0.0-2108 \$					
ce Name						
ay Name						
scription						
	Visible					
tion						
Aanaged Cli	uster					
-	MyCluster		٠			
rver URL	yam.timeline-se	ervice.hostr	iame:8188			
Manager URL	yam.resourcem	anager.hos	tname:8088			
	ter Name erver URL	scription Visible Visible	Seription Visible Vis	scription Si Visible tion Wanaged Cluster ter Name MyCluster s rver URL yam.timeline-service.hostname:8188 Manager yam.resourcomanager.hostname:8088	scription Visible tion Wanaged Cluster ter Name MyCluster yam.Jimeline-service.hostname.8188 Manager yam.resourcemanager.hostname.8088	scription Visible tion Managed Cluster ter Name MyCluster yam.timeline-service.hostname.8188 Manager yam.resourcemanager.hostname.8088

Important

Secure clusters that use wire encryption (SSL/TSL) cannot use the **Local Ambari Managed Cluster** option. Instead you must configure the view as described in the instructions for manually-deployed clusters [87].

5. Click Save, grant Permissions on the view (see User Permissions for Tez Views), and click Go to instance to use the view. See Using the Tez View.

To create a new Tez View instance for a manually-deployed cluster:

- 1. Navigate to the Ambari Administration interface.
- 2. Click Views, expand the Tez View, and click Create Instance.
- 3. On the Create Instance page, select the Version.
- 4. Enter the Details (required). The Instance Name appears in the URI, the Display Name appears in the Views drop-down list, and the Description helps multiple users identify the view.
- 5. Scroll down to the Cluster Configuration, verify that **Custom** is checked and enter the following values, which tell the Tez View how to access resources in the cluster:

Table 14.2. Cluster Configuration Values for the Tez View in Ambari

Property	Value
YARN Timeline Server URL (required)	The URL to the YARN Application Timeline Server, used to provide Tez information. Typically, this is the yarn.timeline-service.webapp.address property that is specified in the etc/hadoop/conf/ yarn-site.xml.
	When you enter the value in the view definition, pre- pend "http://" to the value you find in the yarn-site.xml file. For example, http:// <timeline server<br="">host>:8188</timeline>
	For wire encryption-enabled clusters:
	Set this based on the value of <pre>yarn.timeline- service.webapp.https.address in yarn- site.xml</pre>
	When you enter the value in the view definition, pre- pend "https://" to the value. For example, https:// <timeline host="" server="">:8190</timeline>
YARN ResourceManager URL (required)	The URL to the YARN ResourceManager, used to provide YARN Application data. Typically, this is the yarn.resourcemanager.webapp.address property that is specified in the etc/hadoop/conf/ yarn-site.xml.
	When you enter the value in the view definition, pre- pend "http://" to the value you find in the yarn-site.xml file. For example, http:// <resourcemanager host>:8088</resourcemanager
	Important: If YARN ResourceManager HA is enabled, provide a comma-separated list of URLs for all the Resource Managers.
	For wire encryption-enabled clusters:
	Set this based on the value of yarn.resourcemanager.webapp.https.address in yarn-site.xml
	When you enter the value in the view definition, pre- pend "https://" to the value. For example, https:// <resourcemanager host="">:8090</resourcemanager>

6. Click Save and grant Permissions on the view (see User Permissions for Tez Views).

- 7. At the top of the view instance configuration page, click **Go to instance**.
- 8. When your browser is at the view instance page, copy the URL for the Tez View from your browser address bar:

Figure 14.2. Tez View Instance Page

Lambari.apache.org:8	080/#/main/views/TI	Z/0.5.2.2.2.2.0-43	5/MyTezView				· · · E

- 9. In tez-site.xml, specify the URL that you copied in Step 8 as the value for the tez.tez-ui.history-url.base property, and save the file.
- 10. Restart the HiveServer2 daemon to make sure that your changes to tez-site.xml take effect.

To use the view, see Using the Tez View.

Important

If your cluster is configured for Kerberos, you must set up Ambari Server for Kerberos for the Tez View to access the ATS component. See Kerberos Setup for Tez Views.

2.1. User Permissions for Tez Views

After saving the Tez View instance definition, grant permission on the view for the set of users who can use the view:

/iews / 1	Tez View ៰	Delete Instance
lew	TEZ	
ersion	0.7.0.2.3	0.0-2108
Details		× ta
	Instance Name	TEZ_CLUSTER_INSTANCE
	Display Name	Tez View
	Description	Monitor and debug all Tez jobs, submitted by Hive queries and Pig scripts (auto-created)
		12 March
Permission	15	2 Vable
Permission Permission Use		mission to these users Grant permission to these groups
Permission	a Grant pe	mission to these users Grant permission to these groups
Permission Use Cluster Cor	a Grant pe	mitation to these users Grant permitation to these groups
Permission Use Cluster Cor	a Grant pe	mitation to these users Grant permitation to these groups
Permission Use Cluster Cor	a Grant pe	mission to these users Orant permission to these groups
Permission Use Cluster Cor & Local A	a Grant pe	mission to these users Orant permission to these groups

Figure 14.3. Granting User Permissions to Tez Views

Note

To grant access to all Hive and Pig users, create a group that contains these users, and then grant permission to use the Tez View to that group. See also the Managing Users and Groups in Hortonworks Data Platform Apache Ambari Administration.

2.2. Kerberos Setup for Tez Views

To set up basic Kerberos for views, see <u>Set Up Kerberos for Ambari Server</u> in Hortonworks Data Platform Apache Ambari Security.

After you have set up basic Kerberos for the Tez View, you must set the following configuration properties:

1. On the timeline server host, set the following values for properties in the YARN configuration for Ambari-managed clusters or the <code>yarn-site.xml</code> for manually deployed clusters:

Property	Value
<pre>yarn.timeline-service.http- authentication.proxyuser.\${ambari principal name}.hosts</pre>	*
<pre>yarn.timeline-service.http- authentication.proxyuser.\${ambari principal name}.users</pre>	*

Table 14.3. Kerberos Settings for Tez Views

For example, if the Kerberos principal used for the Ambari server is ambariservice@EXAMPLE.COM, replace \${ambari principal name} with ambariservice.

2. Restart the Timeline Server so your configuration changes take effect.

3. Using the Tez View

Tez provides a framework that enables human-interactive response times with Apache Hive queries and Apache Pig data transformations. The Tez View enables you to understand and debug submitted Tez jobs, such as Hive queries or Pig scripts, that are executed using the Tez execution engine.

The following sections discuss using the Tez Views to manage Hive and Pig tasks:

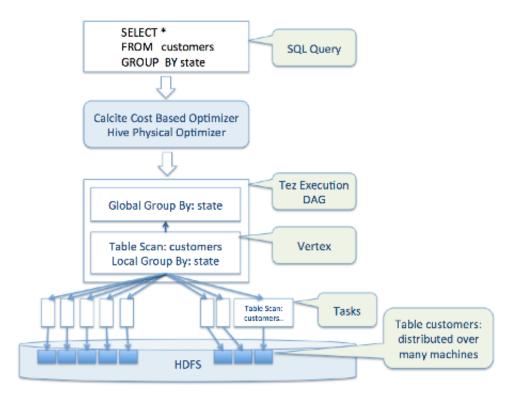

- Understanding Directed Acyclic Graphs (DAGs), Vertices, and Tasks [90]
- Identifying the Tez DAG for Your Job [91]
- Understanding How Your Tez Job Is Executed [92]
- Identifying Causes of Failed Jobs [93]
- Viewing All Failed Tasks [94]
- Using Counters to Identify the Cause of Slow-Performing Jobs [94]

3.1. Understanding Directed Acyclic Graphs (DAGs), Vertices, and Tasks

To explain DAGs, vertices, and tasks, consider how Hive SQL queries are compiled and converted into a Tez execution graph also known as a DAG. A *DAG* is a collection of vertices where each vertex executes a fragment of the query or script. Directed connections between vertices determine the order in which they are executed. For example, the vertex to read a table must be run before a filter can be applied to the rows of that table.

As another example, consider when a vertex reads a user table. This table can be very large and distributed across multiple computers and multiple racks. Reading the table is achieved by running many tasks in parallel. The following figure shows the execution of a SQL query in Hive:

3.2. Identifying the Tez DAG for Your Job

To identify the Tez DAG for your job:

- 1. Navigate to the Tez View instance by clicking **Go to instance** on the Tez View page in Ambari. The Tez View instance page displays a list of jobs sorted by time, listing the latest jobs first. You can search a job using the following fields:
 - **Dag Name** (DAG name for the job)
 - Id (DAG identifier)
 - Submitter (user who submitted the job)
 - Status (job status)
 - Application ID
- 2. When you have entered your search criteria, press **Enter**, and search results matching your criteria are returned below.

Selecting the Columns That Appear in Search Results

To select which columns are included in the Tez View search results, click the gear icon to the right of the search tool bar. A Column Selector dialog box appears where you can select which columns appear in the search results. Select the columns, and click **Ok** to return to the Tez View:

😤 All DAGs	(-		
0	Column Selector ×		un 2015 22:18:55	Ø Retresh
Dag Name Id Search	Select All Filter options		First 1	Nows 0
bag Name Id	Ø Dag Name		Duration	Applice
ive_2015061421444 dag_143430300	2 6 1d	5:06	9 secs	applica
mbari-ga_20150614 dag_14342307	Ø Submitter	8:44	8 secs	applica
mbari-ga_20150614 dag_14342307	Status	7.23	9 secs	applica
OrderedWordCount dag_14342307	S Start Time	8.35	8 secs	applica
fgLatin:pigSmoke.sh dag_14342307	G End Time	17:59	6 secs	applica
	S Duration		-	
	B Application ID			
	S Queue			
	FileSystem - FILE_BYTES_READ			
	FileSystem - FILE_BYTES_WRITTEN			
	FleSystem - FILE_READ_OPS			

Figure 14.5. Tez View Column Selector Dialog Box

Note

To search for columns, use the search well at the top of the Column Selector dialog box. Check **Select All** to include all columns in your search results and uncheck it to clear all of your column selections.

Understanding Tez View Job Status

The following table explains the job status field that is returned for all search results returned in the Tez View:

Table 14.4. Tez Job Status Descriptions

Status	Description
Submitted	The DAG is submitted to Tez but is not running.
Running	The DAG is currently running.
Succeeded	The DAG completed successfully.
Failed	The DAG failed to complete successfully.
Killed	The DAG was stopped manually.
Error	An internal error occurred when executing the DAG.

3.3. Understanding How Your Tez Job Is Executed

The Tez View enables you to gain insight into the complexity and the progress of executing jobs.

The View tab shows the following:

- DAG graphical view
- All vertices
- Tasks per vertex on top right of the vertex
- Failed vertices display in red, successful vertices display in green
- Mouse over vertices to view timeline details

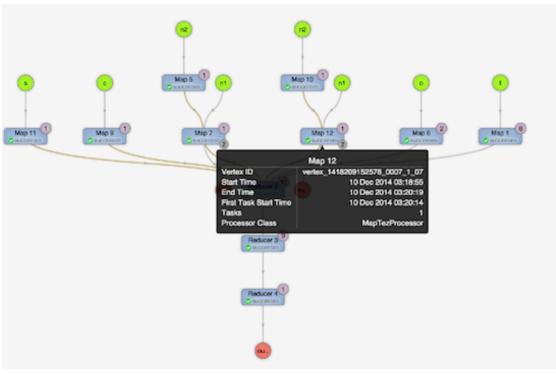

Figure 14.6. View Tab in Tez View

The View Tab enables you to investigate the vertices that have failures or are taking a long time.

3.4. Identifying Causes of Failed Jobs

The Tez View enables you to quickly find and report errors. When a Tez task fails, you must:

- Identify why the task failed
- Capture the reason for task failure

When a Tez task fails, the DAG Details tab explains the failure:

Ambari MyCluster Coops Calerts ▲ admin • Alerts Admin Dashboard Services Hosts All DAGs / DAG [ambari-qa_20150614171710_059670d9-ac45-4913-b828-bafb29078866:1] DAG Details DAG Counters Graphical View All Vertices All Tasks All TaskAttempts Ø Last refreshed at 14 Jun 2015 10:19:01 C Refr DAG Details Application Id application 1434230750579 0006 Entity Id dag 1434230750579 0006 1 User ambari-ga Status FAILED [Failed Tasks] [Failed TaskAttempts] Start Time 14 Jun 2015 10:17:13 14 Jun 2015 10:17:23 End Time Duration 9 6805 Diagnostics Vertex failed, vertexName=Map 1, vertexid=vertex_1434230750579_0006_1_00, diagnostics= » Task falled, taskid=task_1434230750579_0006_1_00_000000, diagnostics= > TaskAttempt 0 failed, info-> Container container_1434230750579_0006_01_000002 finished with diagnostics set to > Container failed, exitCode=1. Figure 14.7. DAG Details Window

3.5. Viewing All Failed Tasks

Multiple task failures may occur. The Tez View All Tasks tab enables you to view all tasks that failed and examine the reason and logs for each failure. Logs for failed tasks, but not for aborted tasks are available to download from this tab:

Figure 14.8. Tez View All Tasks Tab

3.6. Using Counters to Identify the Cause of Slow-Performing Jobs

The Tez View shows counters so you can understand why a task performs more slowly than expected. Counters help you better understand the task size and enable you to locate anomalies. Elapsed time is one of the primary counters to look for.

Counters are available at the DAG, vertex, and task levels:

Monitoring Task Progress for Jobs

The Tez View shows task progress by increasing the count of completed tasks and total tasks. This enables you to identify the tasks that might be "hung" and to understand more about long-running tasks.

15. Using Workflow Designer View -Tech Preview

Ambari includes the Workflow Designer View, which supports monitoring and scheduling jobs on the cluster.

Important

Workflow Designer View is a Tech Preview feature. Expect Workflow Designer View documentation in a future Ambari release.

16. Using Zeppelin View - Tech Preview

Ambari includes the Zeppelin View, which supports creating and editing scripts that run data streaming jobs.

Important

Zeppelin View is a Tech Preview feature. Expect Zeppelin View documentation in a future Ambari release.
