What's new in this release: Apache Hive

HDP 3.0.1 includes partitioning of materialized views, which can improve query responsiveness and maintenance fixes.

HDP 3.0 includes Apache Hive 3 enhancements that can help you improve query performance and comply with regulations. The following list briefly describes a few key enhancements of HDP 3.0 and covers unsupported interfaces.

Workload management

Using workload management, you can configure who uses resources, how much can be used, and how quickly Hive responds to resource requests. Managing resources is critical to Hive LLAP (low-latency analytical processing), especially in a multitenant environment. Using workload management, you can create resource pools and allocate resources to match availability needs and prevent contention for those resources. Workload management improves parallel query execution and cluster sharing for queries running on Hive LLAP, and also improves performance of non-LLAP queries. Workload management reduces resource starvation in large clusters. You implement workload management on the command line using the Hive Query Language.

Transaction processing improvements

Mature versions of ACID (Atomicity, Consistency, Isolation, and Durability) transaction processing and low latency analytical processing (LLAP) evolve in Hive and HDP 3.0. ACID tables are enhanced to serve as the default table type in HDP 3.0, without performance or operational overload. Using ACID table operations facilitates compliance with the right to be forgotten requirement of the GDPR (General Data Protection Regulation). Application development and operations are simplified with stronger transactional guarantees and simpler semantics for SQL commands. You do not need to bucket ACID tables, so maintenance is easier. You no longer need to perform ACID delete operations in a Hive table.

Materialized views

With improvements in transactional semantics comes advanced optimizations, such as materialized view rewrites and automatic query cache. With these optimizations, you can deploy new Hive application types. Because multiple queries frequently need the same intermediate roll up or joined table, you can avoid costly, repetitious query portion sharing, by precomputing and caching intermediate tables into views. The query optimizer automatically leverages the precomputed cache, improving performance. Materialized views increase the speed of join and aggregation queries in business intelligence (BI) and dashboard applications, for example.

Direct, low latency Hive query of Kafka topics

With HDP 3.0, you can create a Druid table within Hive from a Kafka topic in a single command. This feature simplifies queries of Kafka data by eliminating the data processing step between delivery by Kafka and querying in Druid.

Superset

HDP 3 introduces a technical preview of Apache Superset, the data exploration and visualization UI platform. Superset is a way to create HDP dashboards. Using Superset, installed by default as a service in Ambari, you can connect to Hive, create visualizations of Hive data, and create custom dashboards on Hive datasets. Superset is an alternative to Hive View, which is not available in HDP 3.0.

Spark integration with Hive

You can use Hive 3 to query data from Apache Spark and Apache Kafka applications, without workarounds. The Hive Warehouse Connector supports reading and writing Hive tables from Spark.

Hive security improvements

Apache Ranger secures Hive data by default. To meet customer demands for concurrency improvements, ACID support for GDPR (General Data Protection Regulation), render security, and other features, Hive now tightly controls the file system and computer memory resources. With the additional control, Hive better optimizes

workloads in shared files and YARN containers. The more Hive controls the file system, the better Hive can secure data.

Query result cache

Hive filters and caches similar or identical queries. Hive does not recompute the data that has not changed. Caching repetitive queries can reduce the load substantially when hundreds or thousands of users of BI tools and web services query Hive.

Information schema database

Hive creates two databases from JDBC data sources when you add the Hive service to a cluster: `information_schema` and `sys`. All Metastore tables are mapped into your tablespace and available in `sys`. The `information_schema` data reveals the state of the system, similar to `sys` database data. You can query `information_schema` using SQL standard queries, which are portable from one DBMS to another.

Deprecated, unavailable, and unsupported interfaces

In HDP 3.0, Hive does not support the following features:

- WebHCat
- Hcat CLI
- Hive CLI (replaced by Beeline)
- SQL Standard Authorization
- MapReduce execution engine (replaced by Tez)

Apache Hive 3 architectural overview

Understanding Apache Hive 3 major design changes, such as default ACID transaction processing and support for only the thin hive client, can help you use new features to address the growing needs of enterprise data warehouse systems.

Execution engine changes

Apache Tez replaces MapReduce as the default Hive execution engine. MapReduce is no longer supported, and Tez stability is proven. With expressions of directed acyclic graphs (DAGs) and data transfer primitives, execution of Hive queries under Tez improves performance. SQL queries you submit to Hive are executed as follows:

- Hive compiles the query.
- Tez executes the query.
- YARN allocates resources for applications across the cluster and enables authorization for Hive jobs in YARN queues.
- Hive updates the data in HDFS or the Hive warehouse, depending on the table type.
- Hive returns query results over a JDBC connection.

A simplified view of this process is shown in the following figure:

If a legacy script or application specifies MapReduce for execution, an exception occurs. You can set an option to silently ignore a MapReduce setting. Most user-defined functions (UDFs) require no change to execute on Tez instead of MapReduce.

Design changes that affect security

The following Hive 3 architectural changes provide improved security:

- Tightly controlled file system and computer memory resources, replacing flexible boundaries: Definitive boundaries increase predictability. Greater file system control improves security.
- Optimized workloads in shared files and YARN containers

By default, the HDP 3.0 Ambari installation adds Apache Ranger security services. The major authorization model in Hive is Ranger. This model permits only Hive to access HDFS. Hive enforces access controls specified in Ranger. This model offers stronger security than other security schemes and more flexibility in managing policies.

If you do not enable the Ranger security service, or other security, by default Hive uses storage-based authorization (SBA) based on user impersonation.

HDFS permission changes

In HDP 3.0, SBA relies heavily on HDFS access control lists (ACLs). ACLs are an extension to the permissions system in HDFS. HDP 3.0 turns on ACLs in HDFS by default, providing you with the following advantages:

- Increased flexibility when giving multiple groups and users specific permissions
- Convenient application of permissions to a directory tree rather than by individual files

Transaction processing changes

You can deploy new Hive application types by taking advantage of the following improvements in transaction processing:

- Mature versions of ACID transaction processing and LLAP:
 - ACID tables are the default table type in HDP 3.0.
 - ACID enabled by default causes no performance or operational overload.
- Simplified application development, operations with stronger transactional guarantees, and simpler semantics for SQL commands
 - You do not need to bucket ACID tables in HDP 3.0, so maintenance is easier.
- Materialized view rewrites
- Automatic query cache
- Advanced optimizations

Hive client changes

Hive 3 supports only the thin client Beeline for running queries and Hive administrative commands from the command line. Beeline uses a JDBC connection to HiveServer to execute all commands. Parsing, compiling, and executing operations occur in HiveServer. Beeline supports the same command-line options as the Hive CLI with one exception: Hive Metastore configuration changes.

You enter supported Hive CLI commands by invoking Beeline using the hive keyword, command option, and command. For example, `hive -e set`. Using Beeline instead of the thick client Hive CLI, which is no longer supported, has several advantages, including the following:

- Instead of maintaining the entire Hive code base, you now maintain only the JDBC client.
- Startup overhead is lower using Beeline because the entire Hive code base is not involved.

A thin client architecture facilitates securing data in these ways:

- Session state, internal data structures, passwords, and so on reside on the client instead of the server.
- The small number of daemons required to execute queries simplifies monitoring and debugging.

HiveServer enforces whitelist and blacklist settings of Hive configuration properties. Beeline does not support `hive -e set key=value` to configure the Hive Metastore. Using the blacklist, you can restrict memory configuration to prevent HiveServer instability. You can configure multiple HiveServer instances with different whitelists and blacklists to establish different levels of stability.

The change in Hive client requires you to use the `grunt` command line to work with Apache Pig.

Apache Hive Metastore changes

HiveServer now uses a remote instead of an embedded metastore; consequently, Ambari no longer starts the metastore using `hive.metastore.uris=' '`. You no longer set `key=value` commands on the command line to configure Hive Metastore. You configure properties in `hive-site.xml`. The Hive catalog resides in Hive Metastore, which is RDBMS-based as it was in earlier releases. Using this architecture, Hive can take advantage of RDBMS resources in a cloud deployments.

Spark catalog changes

Spark and Hive now use independent catalogs for accessing SparkSQL or Hive tables on the same or different platforms. A table created by Spark resides in the Spark catalog. A table created by Hive resides in the Hive catalog. Although independent, these tables interoperate.

You can access ACID and external tables from Spark using the `HiveWarehouseConnector`.

Query execution of batch and interactive workloads

The following diagram shows the HDP 3.0 query execution architecture for batch and interactive workloads:

You can connect to Hive using a JDBC command-line tool, such as Beeline, or using a JDBC/ODBC driver with a BI tool, such as Tableau. Clients communicate with an instance of the same HiveServer version. You configure the settings file for each instance to perform either batch or interactive processing.

Apache Hive 3 upgrade process

Supplemental information about preparing for an upgrade, upgrading, and using Hive tables after upgrading to Hive 3 helps you achieve a successful HDP and Apache Ambari major upgrade.

Some transactional tables require a major compaction before upgrading to 3.0. Running the Hive pre-upgrade tool identifies the tables that need such a compaction and provides scripts that you run to perform the compaction. Depending on the number of tables and partitions, and the amount of data involved, compactions might take a significant amount of time and resources. The script output of the pre-upgrade tool includes some heuristics that might help estimate the time required. If no script is produced, no compaction is needed.

Compaction cannot occur if the pre-upgrade tool cannot connect to Hive Metastore. During compaction, shutting down HiveServer2 is recommended to prevent users from executing any update, delete, or merge statements on tables during compaction and for the duration of the upgrade process.

You should run the pre-upgrade tool command on the command line after upgrading Ambari 2.6.2.2 to 2.7.x. You do not actually use Ambari to run this command.

The following properties can affect compaction:

- `hive.compactor.worker.threads`
Specifies limits of concurrent compactions.
- `hive.compactor.job.queue`
Specifies the Yarn queue of compaction jobs. Each compaction is a MapReduce job.

The pre-upgrade tool looks for files in an ACID table that contains update or delete events, and generates scripts to compact these tables. You prepare Hive for upgrade to obtain and run the scripts. Assuming you upgraded Ambari at some point, you can then upgrade HDP components, including Hive. After upgrading, check generated logs for any errors. Check that the upgrade process correctly converted your tables.

Changes after upgrading to Apache Hive 3

To locate and use your Apache Hive 3 tables after an upgrade, you need to understand the changes that occur during the upgrade process. Changes to the location of tables, permissions to HDFS directories, table types, and ACID-compliance occur.

Hive changes to ACID properties

Hive 2.x and 3.x have transactional and non-transactional tables. Transactional tables have atomic, consistent, isolation, and durable (ACID) properties. In Hive 2.x, the initial version of ACID transaction processing is ACID v1. In Hive 3.x, the mature version of ACID is ACID v2, which is the default table type in HDP 3.0..

Native and non-native storage formats

Storage formats are a factor in upgrade changes to table types. Hive 2.x and 3.x supports the following Hadoop native and non-native storage formats:

- Native: Tables with built-in support in Hive, such as those in the following file formats:
 - Text
 - Sequence File
 - RC File
 - AVRO File
 - ORC File
 - Parquet File
- Non-native: Tables that use a storage handler, such as the `DruidStorageHandler` or `HBaseStorageHandler`

HDP 3.x upgrade changes to table types

The following table compares Hive table types and ACID operations before an upgrade from HDP 2.x and after an upgrade to HDP 3.x. The ownership of the Hive table file is a factor in determining table types and ACID operations after the upgrade.

Table 1: HDP 2.x and 3.x Table Type Comparison

| HDP 2.x | | | | HDP 3.x | |
|------------|---------|----------------------|---------------------------------|-----------------------------|---------|
| Table Type | ACID v1 | Format | Owner (user) of Hive Table File | Table Type | ACID v2 |
| External | No | Native or non-native | hive or non-hive | External | No |
| Managed | Yes | ORC | hive or non-hive | Managed, updatable | Yes |
| Managed | No | ORC | hive | Managed, updatable | Yes |
| | | | non-hive | External, with data delete* | No |
| Managed | No | Native (but non-ORC) | hive | Managed, insert only | Yes |
| | | | non-hive | External, with data delete* | No |
| Managed | No | Non-native | hive or non-hive | External, with data delete* | No |

* See [Dropping an External Table Along with the Data](#) (link below).

Other HDP 3.x upgrade changes

Managed, ACID tables that are not owned by the hive user remain managed tables after the upgrade, but hive becomes the owner.

After the upgrade, the format of a Hive table is the same as before the upgrade. For example, native or non-native tables remain native or non-native, respectively.

After the upgrade, the location of managed tables or partitions do not change under any one of the following conditions:

- The old table or partition directory was not in its default location /apps/hive/warehouse before the upgrade.
- The old table or partition is in a different file system than the new warehouse directory.
- The old table or partition directory is in a different encryption zone than the new warehouse directory.

Otherwise, the location of managed tables or partitions does change: The upgrade process moves managed files to /warehouse/tablespace/managed/hive. By default, Hive places any new external tables you create in HDP 3.x in /warehouse/tablespace/external/hive.

The /apps/hive directory, which is the former location of the Hive 2.x warehouse, might or might not exist in HDP 3.x.

ACID table conversion

During the upgrade process, you can override the conversion of ACID v1 tables to ACID v2. For example, you can choose to first convert everything except ACID v1 tables to external tables, and then later convert them to ACID tables one by one.

After upgrading, to convert a non-transactional table to an ACID v2 transactional table, you use the ALTER TABLE command and set table properties to 'transactional=true'. For example:

```
ALTER TABLE T3 SET TBLPROPERTIES ('transactional'='true');
```

Install the Hive service

In Ambari, you install the Hive service as you would any other service, and in the process, you configure Hive to use a database for the Hive Metastore.

Procedure

1. Configure a database for the Hive Metastore.

- Choose to use an existing database suitable for production work and perform the next step.
- Choose an Ambari installed database, such as MySQL, suitable for development work only, and skip the next step.

2. If you chose an existing database in the last step, create a hive user and database.

If Ambari installs the database, you do not need to create a hive user and database.

For example, create user named hive and a database named hive, using the following command, but substituting a password of your choosing for [HIVE_PASSWORD] and the Hive MetaStore FQDN for [HIVE_METASTORE_FQDN]:

```
# mysql -u root -p
CREATE USER 'hive'@'localhost' IDENTIFIED BY '[HIVE_PASSWORD]';
```

```
GRANT ALL PRIVILEGES ON *.* TO 'hive'@'localhost';

CREATE USER 'hive'@'%' IDENTIFIED BY '[HIVE_PASSWORD]';
GRANT ALL PRIVILEGES ON *.* TO 'hive'@'%' ;

CREATE USER 'hive'@[HIVE_METASTORE_FQDN] IDENTIFIED BY
'[HIVE_PASSWORD]';
GRANT ALL PRIVILEGES ON *.* TO 'hive'@[HIVE_METASTORE_FQDN]';

FLUSH PRIVILEGES;

CREATE DATABASE hive;
```

3. Obtain the JDBC driver for the database to the Ambari server node, and as root, set up the driver:

```
ambari-server setup --jdbc-db=<database name> --jdbc-driver=<path to driver>
```

4. In Ambari Services > Hive > Configs, test the connection to the database.
5. Follow prompts from the Ambari wizard to complete the installation.
